(54) Title: DIAGNOSTICS AND THERAPY OF EPSTEIN-BARR VIRUS IN AUTOIMMUNE DISORDERS

(57) Abstract

Data consistent with autoimmune disease being caused by Epstein-Barr virus are shown. Based on this evidence, an effective vaccine would prevent the autoimmune disease in those vaccinated, modified or administered so that the vaccine is not itself capable of inducing autoimmune disease. In the case of anti-Sm, structures to be avoided in Epstein-Barr virus-derived vaccine have been identified. Differences have been identified in the immune responses to Epstein-Barr infection between individuals who develop a specific autoimmune disease and those who do not. These differences are used to distinguish those who are at greater risk for developing specific autoimmune diseases from those who are at lesser risk. Assuming Epstein-Barr virus causes autoimmune disease and that Epstein-Barr virus remains latent in the patient for life, reactivation of the virus from the latent state is important in generating or maintaining the autoimmune response that culminates in autoimmune disease. Cells infected with latent virus may also encourage autoimmunity. Based on the understanding that reactivation or latency are important to produce or sustain autoimmunity, then therapies directed against Epstein-Barr virus will also be effective therapies for the autoimmune manifestations of disease for which Epstein-Barr virus is responsible.

DIAGNOSTICS AND THERAPY OF EPSTEIN-BARR VIRUS IN AUTOIMMUNE DISORDERS

U.S. GOVERNMENT RIGHTS

The U.S. Federal Government has rights in this invention by virtue of Grant NO. RO1 AR42460 to John B. Harley and KO8 AR01981 to Judith A. James from the National Institutes of Health.

5

Background of the Invention

This is in the area of the prevention, diagnosis, and treatment of autoimmune diseases having Epstein-Barr virus as an etiological agent.

Epstein-Barr virus infects B cells and induces a large number of different autoantibodies in the early phase of infection. The B cell 10 proliferation and autoantibody production is eventually brought under control in nearly everyone by virus specific T cells. Thereafter, the virus remains latent, surviving in the host for the remainder of the natural life. Once the host is infected the virus continues to "reactivate" at a low level. Evidence for this reactivation is the shedding of virus in the oral cavity, 15 infection through exchange of oral secretions, the spontaneous *in vitro* outgrowth of transformed B cells, and the spontaneous production of Epstein-Barr virus *in vitro*. The continuous presence of virus presents a significant challenge to the immune system and requires that the immune mechanisms sustain viral suppression over the many decades of remaining life. If Epstein-Barr virus causes autoimmune disease, then this feature, 20 the sustained presence of a low level of virus in the host continuously emerging from latency, is likely to be important in diseases that appear long after the original infection by Epstein-Barr virus.

Epstein-Barr virus is a herpes virus and is also called Human 25 Herpes Virus 4. This virus is from the genus *Lymphocryptovirus* and subfamily gammaherpesvirinae. This is the only gamma herpes virus known in man. There are several very good reviews of the biology and structure of Epstein-Barr virus. The reader is referred to classic reviews (Kieff, E. and Liebowitz, D.: Epstein-Barr virus and its replication. In

-2-

Virology, 2nd ed. Fields et al., eds. pp 1889-1921 (Raven Press, New York 1990); Miller, G.: Epstein-Barr virus. *ibid.* pp. 1921-1958; Evans, A.S. and Niederman, J.C.: Epstein-Barr virus. In *Viral Infections in Humans*, 3rd ed. Evans, A.S. ed. pp 265-292 (Plenum, New York City 1989)). Like the other herpes viruses, this is a DNA virus and has a strong propensity for latency. Once latent this virus emerges from latency at a low level throughout life. Epstein-Barr virus induces lymphoma in some non-human primates. In man Epstein-Barr virus appears to be responsible for at least infectious mononucleosis, Burkitt's lymphoma and nasopharyngeal carcinoma.

Epstein-Barr virus infects the epithelium of the upper airway, B cells and a few T cells. On B cells the viral receptor is the Complement Receptor, Type 2, also known as the CR2 receptor. Infected B cells are able to present antigen, though the virus has recently been found to produce inhibitors of antigen processing (Levitskaya, J. Nature 375:685-688 (1995)), and to synthesize a molecule similar to IL-10 which has profound local effects (Suzuki, T. et al J. Exp. Med. 182:477-486 (1995)). Depending upon what genes are expressed, latently infected B cells may not respond to stimuli in the usual way and may not provide the signals, either qualitatively or quantitatively, that would otherwise be provided. Such aberrant influences upon the normal immune response may provide the basis for subsequent autoimmune disease in some people.

Epstein-Barr virus has been known for more than three decades. For the specific example of an autoimmune disease used herein to illustrate the principles of the invention, many others have considered a relationship between systemic lupus erythematosus and Epstein-Barr virus. The size of the separate literatures concerning lupus, on the one hand, and Epstein-Barr virus on the other are too vast to comprehensively review here. Nevertheless, over 25 years ago antibody titers were noted to be elevated against a number of viruses including rubella, measles, and parainfluenza 1 (Hollinger, F.B. et al. Bact. Proc. 131:174 (1970); Phillips, P.E. and Christian, C.L. Science 168:982-4 (1970); Hurd, E.R.

-3-

et al. Arthritis Rheum. 13:724-33 (1970)). Perhaps, Dalldorf and colleagues were the first to report an evaluation of the titers of antibody against Epstein-Barr virus in lupus patients; they found no difference between lupus patients and normal controls (Dalldorf, G. et al. J. Am. Med. Assn. 208:1365-8 (1969)).

5 In contrast, Evans and colleagues claimed to find elevated titers of anti-Epstein-Barr antibodies relative to controls (Evans, A.S., et al. Lancet 1:167-168 (1970)). This paper generated a number of responses, all of which encouraged caution in interpreting these results or address the 10 potential artifacts which could confuse the interpretation (Newell, G.R. and Stevens, D.A. Lancet 1:652 (1971); Evans, A.S. Lancet 1:1023-4 (1971); Gergely, L. et al. Lancet 1:325-326 (1973); Evans, A.S. and Rothfield, N.F. Lancet 1:1127-1128 (1973); Phillips, P.E. et al. Lancet 1:1449 (1973)). Much of the confusion arises from the use of 15 immunofluorescence assays for the detection of anti-Epstein-Barr virus seroconversion. This investigative activity culminated in a remarkable study in which many participants of the controversy combined their resources to develop data they interpreted to show, "the combined approach used in this study fails to provide supportive evidence that E.B. 20 virus is a causative agent in the connective-tissue diseases" (Klippel, J.H. et al. Lancet 2:1057-1058 (1973)). They found no difference in the titer of antibodies against Epstein-Barr virus in lupus compared to controls.

A Japanese group found a high frequency of antibodies against 25 Epstein-Barr virus Nuclear Antigens 2 and 3 in lupus patient sera, compared to normal controls (Kitagawa, H., Et al. Immunol. Lett. 17:249-252 (1988)). Another Japanese group found higher levels of antibody directed against a membrane antigen from Epstein-Barr virus in lupus (and rheumatoid arthritis) sera than in controls (Yokochi, T. et al. J. Rheumatol. 16:1029-1032 (1989)). Similarly, an Australian group 30 found a modest increase in antibodies against early antigens (Sculley, D.G., et al. J. Gen. Virol. 67:2253-2258 (1986)).

-4-

An Italian group has shown that the affinity purified antibodies from the 95-119 region of Sm D from lupus patients bind the Epstein-Barr virus Nuclear Antigen-1 between amino acids 35 and 58 (Sabbatini, A., et al. Eur. J. Immunol. 23:1146-1152 (1993)).

5 The most recent contribution to this question uses both molecular methods to detect Epstein-Barr DNA and serologic methods to detect antibodies (Tsai, Y. et al. Int. Arch. Allergy Immunol. 106:235-240 (1995)). This study also shows no significant differences between lupus patients and controls.

10 Other diseases, including both rheumatoid arthritis and Sjogren's syndrome, have been explored for a possible relationship to Epstein-Barr virus. Robert Fox and colleagues presented their conception of this area in 1992 (Fox R.I., Luppi, M. and Kang H. J. Rheumatol. 19:18-24 (1992)). The evidence which they conclude supports a role for Epstein-15 Barr virus in rheumatoid arthritis includes: similarity between synovial and viral antigens, higher levels of antibodies against the Epstein-Barr virus Nuclear Antigens 1 and 3, and the lower ability of lymphocytes to prevent the outgrowth of autologous, Epstein-Barr virus infected lymphocytes (Fox, R.I. Current Opin. Rheum. 7:409-416 (1995)). Others 20 have found a small increase in the frequency of latency for Epstein-Barr virus in rheumatoid arthritis, but a much larger effect for Human Herpes virus-6 (Newkirk, M.M. et al. Br. J. Rheum. 33:317-322 (1994)).

In Sjogren's syndrome Fox and colleagues note the higher level and frequency of Epstein-Barr virus in salivary gland epithelium and 25 gland tissue (Fox, R.I. et al. J. Immunol. 137:3162-3168 (1986)). Other viruses have also been considered by this author (Fox, R.I. Current Opin. Rheum. 7:409-416 (1995)).

Others have developed interesting data from Sjogren's syndrome. Pflugfelder and colleagues found evidence for Epstein-Barr virus in 80% 30 of the lacrimal gland specimens from Sjogren's syndrome patients and in none of the controls (Pflugfelder, S.A. et al Ophthalmology 97:976-984 (1990); and Pflugfelder, S.A. et al. Am. J. Pathol. 143:49-64 (1993)).

-5-

Karameris and colleagues found higher levels of hybridization between an Epstein-Barr virus DNA probe and the nuclei of salivary gland epithelial cells in Sjogren's syndrome than in controls (Karameris, A. et al. Clin. Exp. Rheum. 10:327-332 (1992)).

5 Others, however, found no such relationship and concluded that the frequency of Epstein-Barr virus DNA in salivary biopsy specimens was no different in patients with Sjogren's syndrome when compared with normals (Venables, P.J.W., et al. Clin. Exp. Immunol. 75:359-364 (1989); Venables, P.J.W., et al. J. Autoimmunity 2:439-438 (1989));

10 10 Deacon, L.M., et al. Am J. Med. 92:453-454 (1992)). The data collected by Venables and colleagues were interpreted to show that there was "no evidence that the Epstein-Barr virus infection load is increased... [in Sjogren's syndrome]" (Venables, P.J.W. et al. Clin. Exp. Immunol. 75:359-364 (1989)), which is similar to the results of Maitland (Maitland, N.J. Am. J. Med. 96:97 (1994)). Venables and colleagues also refuted there being any abnormality in the serologic response of Sjogren's syndrome patients to Epstein-Barr virus (Deacon, E.M., et al. J. Pathol. 163:351-360 (1991)), citing their data as well as the negative serologic results of Mariette and colleagues (Mariette, X., et al. Am. J. Med. 90:286-294 (1991)).

A Japanese group found an increase in the Epstein-Barr virus production by B cells in patients with Sjogren's syndrome (Tateishi, M. et al. Arthritis Rhuem. 36:827-835 (1993)).

25 25 Also, Inoue and colleagues found a minor increase in antibody levels against Epstein-Barr virus Nuclear Antigen-2 domains in Sjogren's syndrome compared to controls (Inoue, N. et al. J. Infect. Dis. 164:22-28 (1991)). Another Japanese group reported a modest elevation of anti-Epstein-Barr Nuclear antigen, anti-Early Antigen and anti-Epstein-Barr virus Viral Capsid Antigen (all measured by immunofluorescence) (Toda, I., et al. Sjogren's syndrome (SS) and Epstein-Barr virus (EBV) reactivation. In Lacrimal Gland, Tear Film, and Dry Eye Syndrome. D.A. Sullivan, ed. pp 647-650 (Plenum Press, New York 1994)).

-6-

Nevertheless, Whittingham has proposed that Epstein-Barr virus is an etiologic agent for Sjogren's syndrome (Whittingham, S., et al. Med. Hypothesis 22:373-386 (1987)). She and her colleagues imagine that the Epstein-Barr viral RNAs called EBER 1 and EBER 2, which are known 5 to bind the La autoantigen, facilitate overcoming tolerance to La and generating autoimmunity. They postulate that the combined effect of Epstein-Barr virus infection and autoimmunity leads to Sjogren's syndrome.

Morshed and colleagues published data showing an increased level 10 of Epstein-Barr virus DNA in patients with primary biliary cirrhosis compared to controls from peripheral blood mononuclear cells, saliva, and fixed liver tissue (Morshed, S.A. et al. Gastroenterol. Jpn. 27:751-758 (1992)). The nuclear dot antigen is an autoantigen bound by autoantibody found in a few sera from patients with primary biliary cirrhosis. This 15 autoantibody is also uncommonly found in lupus and rheumatoid arthritis sera. Analysis of the epitopes of the nuclear dot antigen has revealed two epitopes which have homology with Epstein-Barr virus protein sequences (Xie, K. and Snyder, M. Proc. Natl. Acad. Sci. 92:1639-1643 (1995)).

An example of double infection with Epstein-Barr virus and 20 another virus is found in a cell line isolated from a patient with apparent multiple sclerosis (Haahr, S. et al. Ann. N. Y. Acad. Sci. 724:148-156 (1996)). The increased prevalence of seroconversion among multiple sclerosis patients, relative to controls, has led to the suggestion that Epstein-Barr virus may be an etiologic agent in multiple sclerosis 25 (Sumaya, C.V. et al. Ann. Neurol. 17:371-377 (1985); Bray, P.F., et al. Arch. Neurol. 40:406-408 (1983); Larsen, P.D., et al. Neurology 35:435-438 (1985); Warner, H.B. and Carp, R.I. Med. Hypothesis 25:93-97 (1988); Bray, P.F. et al. Neurology (1992)).

Because of evidence implicating Epstein-Barr virus in infectious 30 mononucleosis, B cell lymphoma (in immunocompromised hosts), burkitt's lymphoma, nasopharyngeal carcinoma, and some cases of Hodgkin's lymphoma, there has been some activity building toward a

vaccine against Epstein-Barr virus (Morgan, A.J., et al. J. Med. Virol. 29:74-78 (1989); and Morgan, A.J. Vaccine 10:563-571 (1992)). Recombinant vectors expressing gp340/220 in a bovine papillomavirus vector or in an adenovirus vector protected five of six cottontop tamarins

5. from lymphomas that otherwise occur after infection with Epstein-Barr virus (Finerty, S., et al. J. Gen. Virol. 73:449-453 (1992)). A subunit of the gp340/200 in alum protected three of five cotton top tamarins from lymphomas (Finerty, S., et al. Vaccine 12:1180-1184 (1994)), suggesting that this strategy might not be especially effective. A trial of an Epstein-

10. Barr virus vaccine of gp340/220 in a Vaccinia virus vector has been reported from China and failed to protect a third of those immunized (Gu, S. et al. Dev. Biol. Stand. 84:171-177 (1995)).

A variety of therapies have been attempted against Epstein-Barr virus. These include inducing the lysis cycle in cells latently infected by

15. virus (Gutierrez, M.I., et al. Cancer Res. 56:969-972 (1996)). Patients with the Epstein-Barr virus related lymphomatoid granulomatosis have been treated with interferon-alpha 2b with the preliminary impression that the treatment was successful (Wilson, W.H., et al. Blood 87:4531-4537 (1996)). Cycloheximide has been demonstrated to be useful *in vitro*

20. (Ishii, H.H., et al. Immunol. Cell Biol. 73:463-468 (1995)). Therapy with a T cell line has been attempted (Kimura, H. et al. Clin. Exp. Immunol. 103:192-298 (1996)), as has adoptive transfer of gene-modified virus-specific T lymphocytes (Heslop, H.E. et al. Nature Med. 2:551-555 (1996)). Data available do not appear to particularly support the use of

25. acyclovir for Epstein-Barr virus infections (Wagstaff, A.J., et al. Drugs 47:153-205 (1994)), though FK506 (a relative of cyclosporine) may have some benefit (Singh, N., et al. Digestive Dis. Sci. 39:15-18 (1994)). Monoclonal antibodies have been used to treat the virus-induced

30. lymphoproliferative syndrome (Lazarovots, A.I., et al. Clin. Invest. Med. 17:621-625 (1994)).

-8-

It is therefore an object of the present invention to provide strategies to prevent autoimmune disease by vaccination with vaccines based upon Epstein-Barr virus or upon the structure of Epstein-Barr virus.

It is a further object of this invention to provide vaccines based 5 upon Epstein-Barr virus or upon the structure of Epstein-Barr virus which will have little risk of inducing autoimmune disease.

It is a further object of this invention to provide diagnostics which will identify people exposed to Epstein-Barr virus who are at an increased 10 risk for autoimmune disease and, alternatively, those who are at decreased risk for developing autoimmune disease.

It is a further object of this invention to provide for the application of antiviral therapy directed against Epstein-Barr virus in the treatment of autoimmune disease.

It is a further object of this invention to provide diagnostics and 15 therapeutics for autoimmune disease based upon the changes induced by the host by Epstein-Barr virus.

Summary of the Invention

Data consistent with autoimmune disease being caused by Epstein-Barr virus are shown. Some of the features of the mechanism in the 20 specific example of the anti-Sm autoantibody response were found in systemic lupus erythematosus. Based on this evidence, an effective vaccine would prevent the autoimmune disease in those vaccinated, modified or administered so that the vaccine is not itself capable of inducing autoimmune disease. In the case of anti-Sm, structures to be 25 avoided in an Epstein-Barr virus-derived vaccine have been identified.

Differences have been identified in the immune responses to Epstein-Barr infection between individuals who develop a specific 30 autoimmune disease and those who do not. These differences are used to distinguish those who are at greater risk for developing specific autoimmune diseases from those who are a lesser risk.

Assuming Epstein-Barr virus causes autoimmune disease and that Epstein-Barr virus remains latent in the patient for life, reactivation of the virus from the latent state is important in generating or maintaining the autoimmune response that culminates in autoimmune disease. Cells infected with latent virus may also encourage autoimmunity. Based on the understanding that reactivation or latency are important to produce or sustain autoimmunity, then therapies directed against Epstein-Barr virus will also be effective therapies for the autoimmune manifestations of disease for which Epstein-Barr virus is responsible.

10 Brief Description of the Drawings

Figures 1A-D, graphs of absorbance indicative of the antigenicity of overlapping octapeptides of an Sm B/B' polypeptide. Each number along the abscissa indicates the first amino acid of an octapeptide that begins with this amino acid (octapeptide number, 1-8, 2-9, 3-10, etc.).

15 Each octapeptide overlaps its neighbor by seven amino acids. Figure 1A shows the background reactivity of the octapeptides with anti-human IgG conjugate alone. Figure 1B shows the reactivity of the octapeptides with a normal human serum. Figure 1C shows binding of a serum from a patient with systemic lupus erythematosus who precipitates the nRNP 20 autoantigen, but not Sm autoantigen. Figure 1D demonstrates the reactivity of a representative patient who has both anti-Sm and anti-nRNP autoantibodies as determined by specific precipitin formation in Ouchterlony immunodiffusion. From J.A. James and J.B. Harley (J. Immunol. 148:2074-2079, 1992).

25 Figure 2. Mean binding to overlapping octapeptides by Sm and
nRNP precipitin positive lupus patients showing the major epitopes (as
defined as being greater than 0.5 O.D., or a mean of 10 standard
deviations above the mean binding of normal sera). Binding below the
threshold of 0.325 O.D., or the mean of normals plus two standard
30 deviations, has been omitted for clarity. The standard error is depicted as
an open box below the mean in the bar representing the mean of the lupus

-10-

patient binding. From J.A. James and J.B. Harley (J. Immunol. 148;2074-2079, 1992).

Figure 3 is a graph of binding to selected peptides from the B/B', C and D spliceosomal proteins and from Epstein-Barr virus nuclear antigen-1 proteins (PPPGRRP (SEQ ID NO:1), GRGRGRGG (SEQ ID NO:2), and RGRGREK (SEQ ID NO:3)) in six lupus patient sera (which are anti-Sm and anti-nRNP precipitin positive) (black) and five control sera (shown overlaid in white). The peptides shown are, in order, SEQ ID NO:4, SEQ ID NO:5, SEQ ID NO:6, SEQ ID NO:1, amino acids 1 to 10 of SEQ ID NO:9, SEQ ID NO:2, and SEQ ID NO:3.

Figures 4A-D are graphs of the development of an anti-Sm B/B' response in one anti-Sm and anti-nRNP precipitin positive patient. Binding to 211 octapeptides of Sm B/B' is presented as absorbance (X 1000) at 405 nm. Figure 4A presents an example of the background binding found from a normal human serum. Figure 4B presents the binding of the first serum available after presentation with lupus (from April, 1986) and Figure 4C and 4D present the binding of subsequent sera (from July, 1987 and December 1988, respectively). Solid arrows indicate the PPPGMRPP (SEQ ID NO:4) octapeptides and the open arrow the PPPGIRGP (SEQ ID NO:5) sequence. From J.A. James et al (J. Exp. Med. 181:453-461 (December 1995)).

Figures 5A-C are graphs of the binding of PPPGRRP-MAPTM (SEQ ID NO:1) -immunized rabbit sera and a Freund's control serum to the PPPGRRP-MAPTM (Figure 5A SEQ ID NO:1), PPPGMRPP-MAPTM (Figure 5B SEQ ID NO:4), and nRNP/Sm antigen (Figure 5C) by solid phase ELISAs (enzyme-linked immunosorbent assays). The bleeds of the rabbits are along the abscissa and the absorbance (X 1000) on the ordinate. The preimmune serum (pb) and post-immunization bleeds 1 through 14 (Im1 to Im14) which span 52 weeks are indicated. The PPPGRRP (SEQ ID NO:1) peptide is found in the Epstein-Barr virus Nuclear Antigen-1 (EBNA-1).

-11-

Figures 6A-D are graphs of the binding of two rabbit sera to the overlapping octapeptides of the spliceosomal proteins B/B' (Figures 6A and 6C) and D (Figures 6B and 6D). The two rabbits (numbers 40 and 41) were immunized with PPPGRRP-MAPTM (SEQ ID NO:1) 86 days earlier. The serum in Figures 5A and 5B binds to nRNP/Sm, and is positive in the antinuclear antibody assay and the anti-double stranded DNA assay (*Crithidia lucilea* kinetoplast fluorescence assay) while the serum from the second rabbit was not positive in any of these other assays.

Figure 7 is a graph of the binding to the peptide
GAGAGAGAGAGAGAGAGAGAGAGAGAGA (SEQ ID NO:7) from Epstein-Barr virus Nuclear Antigen-1 by lupus sera who all had anti-Sm and anti-nRNP precipitins, as compared to normal control sera.

Figures 8A-E are graphs of the binding to the overlapping octapeptides from Epstein-Barr virus Nuclear Antigen-1. Each octapeptide overlaps its neighbor by seven amino acids. Most of the glycine-alanine repeat has been omitted to avoid unnecessary redundancy. The binding of three controls are presented in Figures 8A, 8B and 8C and that of two lupus sera in Figures 8D and 8E. Figure 8A is from a normal who has no evidence of having been infected by Epstein-Barr virus by the assay for anti-Epstein-Barr virus Viral Capsid Antigen IgG. The other sera presented (Figures 8B through 8E) are all positive in this assay.

Detailed Description of the Invention

In the United States, about 95% of the adult population has been, and continues to be, infected with Epstein-Barr virus. Observations described herein are consistent with a small proportion of these developing autoimmune disease, related to this virus. Other factors are also likely to be important in the development of autoimmune disease, but are not essential to understand in order to develop therapeutics and diagnostics for use in diagnosing, treating and preventing or ameliorating autoimmune diseases involving Epstein-Barr virus as the etiologic agent.

-12-

Epstein-Barr virus is the probable etiologic agent for nearly all cases of lupus, which serves as an example of autoimmune disease.

Diagnostics and therapeutics derived from the discovery that Epstein-Barr virus causes autoimmune disease as applied to the

5 prevention, diagnosis and treatment of autoimmune disease are described herein. Systemic lupus erythematosus (lupus) is the particular autoimmune disease evaluated and for which data have been obtained. Within lupus, the work on a molecular understanding of the relationship between anti-Sm and systemic lupus erythematosus and the relationship of

10 anti-Sm autoantibodies to Epstein-Barr virus is the best illustration of the data supporting these diagnostics and therapeutics.

The experiments described herein to address Epstein-Barr virus in lupus were guided by the results of immunochemical studies, not by the previous studies. These data pointed toward a curious mechanism in the

15 anti-Sm autoantibody system in lupus which could involve Epstein-Barr virus.

The technology applied to the problem is very important in two ways. First, the assays for anti-Epstein-Barr virus antibodies have been dramatically improved. The classic method is to evaluate antibody

20 binding to an Epstein-Barr virus infected cell line by immunofluorescence. This assay is dependent upon the expression of different Epstein-Barr virus proteins, depending upon whether the cell line is producing virus or the virus is latent. The autoantibodies of lupus often render these assays uninterpretable, making their use in lupus especially problematic.

25 Consequently, solid phase assays using enriched preparations of the surface antigen constitute a major improvement. The surface antigen is largely composed of a glycoprotein called gp340/220 or the Viral Capsid Antigen. These preparations of surface antigens have had many interfering substances removed. Epstein-Barr virus infection in man

30 virtually always generates antibodies against this surface antigen. The assay is much simpler than is the cell line immunofluorescence assay and subject to much less variation in interpretation.

-13-

Second, molecular methods have been designed and developed to detect Epstein-Barr virus which appear to be at least as reliable as the serologic methods, and may even be superior. In normal adults Epstein-Barr virus infects only about one in every 20,000 to 500,000 B cells

5 (Miyashita, E. M. et al. Cell 80:593-601 (1995)). B cells usually constitute only about 8% of the peripheral blood mononuclear cells. The vanishingly small quantity of Epstein-Barr DNA is lost in a relative ocean of genomic human DNA and is very difficult to detect. The improved sensitivity and specificity of detection of Epstein-Barr virus DNA

10 improves the measurement made and leads to more accurate interpretation of the data. The older methods detected Epstein-Barr virus DNA in the peripheral blood in about 70% of individuals who had serologically converted, while the method described herein appears to detect more than 95% of those who have seroconverted and a few who have not

15 seroconverted.

Reliable assays were used to address the prevalence of seroconversion and infection in the cases and controls in a way that took optimal advantage of the known properties of the viral infection. Others have selected sub-optimal study populations, have poorly chosen their

20 controls, or have focused upon the quantitative level of antibody rather than qualitative evidence for infection, in addition to the technical problems outlined above in reliably detecting anti-Epstein-Barr virus seroconversion and Epstein-Barr viral DNA.

The data in the anti-Sm autoantibody system, discussed below, are

25 used as a model in which the antigen presenting capacity of the B cell is important in generating autoimmunity. For example, the PPPGRRP (SEQ ID NO:1) structure is found in Epstein-Barr virus Nuclear Antigen-1. This sequence induced autoimmunity against the Sm B/B' of a rabbit after immunization. This autoimmunity not only included the related

30 PPPGMRPP (SEQ ID NO:4) of Sm B/B', but also many other structures of B/B'. When the B cell generates a receptor that binds PPPGRRP (SEQ ID NO:1) and PPPGMRPP (SEQ ID NO:4) then this B cell is

-14-

capable of presenting the spliceosome to the immune system. Of course, once this cross reacting autoantibody is produced, then it may facilitate spliceosomal autoimmunity. Epstein-Barr virus is important because the immune control of the infected B cell is altered by the infection,
5 rendering autoimmunity more likely. This mechanism can be directly extended to other antigens to generate other immune responses (both cellular and humoral) which lead to a variety of autoimmune diseases. Also, double infection with Epstein-Barr virus and another virus would extend the immune regulatory abnormalities to the antigens of the second
10 virus.

Autoimmune Diseases

There are a large number of disorders in man that are thought to be autoimmune. These include systemic lupus erythematosus, autoimmune thyroid disease (Graves' disease or Hashimoto's thyroiditis),
15 autoimmune beta islet disease of the pancreas (more commonly referred to as juvenile or Type 1 diabetes mellitus), primary biliary cirrhosis and many others. The particular disorders listed above are thought to involve antibodies produced in the host (the patient, in this instance) which bind to constituents of self. These antibodies are called autoantibodies. The
20 particular constituent of self bound by the autoantibodies is associated with the different disorders. For example, anti-mitochondrial autoantibodies are associated with primary biliary cirrhosis. Anti-acetylcholine receptor autoantibodies are associated with myasthenia gravis. The list of such autoantibodies is quite long and often only one or
25 a few autoantigens are bound by autoantibodies in each particular disorder. Systemic lupus erythematosus (or abbreviated as lupus herein) is an exception to this tendency, since many autoantibodies may be found in the disease and since patients do not necessarily share any particular autoantibody specificity. Anti-Sm (which is an anti-spliceosomal
30 autoantibody specificity) is one of the autoantibodies closely associated with systemic lupus erythematosus, but even this autoantibody is found in only a minor fraction of patients with systemic lupus erythematosus.

-15-

(Please refer to a review of this area (Harley, J.B. and Gaither, K.K. Rheum. Dis. Clin. N. Amer. 14:43-56 (1992)).

It is not sufficient just to produce autoantibodies. There must be some consequence of their presence in order to develop pathology which 5 culminates in clinical disease. There are many instances of detecting autoantibodies in the absence of any detectable clinical illness.

Autoantibodies may realize their pathologic potential by binding their antigen in the circulation. They then become part of circulating immune complexes. They may deposit in tissues, induce an inflammatory 10 response, and cause tissue injury, as appears to occur in lupus.

Autoantibodies may interfere with the functioning of receptors or otherwise activate cells as may happen in Wegener's granulomatosis or Graves' ophthalmopathy. Autoantibodies may simply block normal functioning of a protein, as happens to the acetylcholine receptor in 15 myasthenia gravis. No doubt there are other mechanisms by which autoantibodies encourage clinical illness.

These mechanisms involve humoral autoimmunity; that is, autoimmunity that is mediated by autoantibodies. There is another form of autoimmunity mediated by cells, in particular T cells. Multiple 20 sclerosis is thought by some to be an example of a disease that is mediated by autoimmune T cells. Although the methods and compositions described herein are particularly concerned with humoral autoimmunity, it is expected that cellular autoimmune processes are also involved with producing autoimmunity as a consequence of Epstein-Barr 25 virus infection. As in many situations, one skilled in the art would expect cellular immune mechanisms to dominate in some individuals and humoral mechanisms to dominate in others. This situation would be expected to give rise to different clinical expression of disease. Tuberculous and lepromatous leprosy are examples where differences in the dominant form 30 of the immune response lead to profound differences in the clinical illness, despite being caused by the same organism.

-16-

The traditional distinction between humoral and cellular immune mechanisms are being reevaluated under a new paradigm. T cells appear to have the capacity to respond in at least two ways. These cells are called Th1 and Th2, for T helper cells, Type 1 and 2. Characteristic 5 cytokine production profiles are often used to distinguish these different responses. Th1 responses tend to be the more traditionally appreciated cellular immune responses. Th2 responses lead, among other consequences, to more of an antibody response and are more aligned with the classic humoral response. However, these boundaries do not appear 10 to operate strictly since some types of antibody are more likely found in Th1 responses and the Th2 response clearly has its cellular component. Most autoimmune diseases probably have important components of both humoral and cellular autoimmunity.

Below, systemic lupus erythematosus is used as a particular 15 example of an autoimmune disease. Data are presented which is consistent with the position that Epstein-Barr virus causes this autoimmune disorder. Lupus is one of many autoimmune diseases that are likely to share basic features, such as the causative agent being Epstein-Barr virus.

20 *Definitions:*

As used herein, autoimmune diseases are diseases that are primarily autoimmune, as well as diseases which do not appear to be primarily autoimmune but have immune manifestations involving immunoglobulins, antigen specific B cell surface receptors (surface 25 immunoglobulin), or antigen-specific T cell receptors. Examples of diseases which fall into these categories are systemic lupus erythematosus, Sjogren's syndrome, rheumatoid arthritis, juvenile onset diabetes mellitus, Wegener's granulomatosis, inflammatory bowel disease, polymyositis, dermatomyositis, multiple endocrine failure, Schmidt's syndrome, 30 autoimmune uveitis, Addison's disease, adrenalitis, primary biliary cirrhosis, Graves' disease, thyroiditis, Hashimoto's thyroiditis, autoimmune thyroid disease, pernicious anemia, gastric atrophy, chronic

-17-

hepatitis, lupoid hepatitis, atherosclerosis, presenile dementia,
demyelinating diseases, multiple sclerosis, subacute cutaneous lupus
erythematosus, hypoparathyroidism, Dressler's syndrome, myasthenia
gravis, autoimmune thrombocytopenia, idiopathic thrombocytopenic
5 purpura, hemolytic anemia, autoimmune hemolytic anemia, pemphigus
vulgaris, pemphigus, bullous pemphigoid, dermatitis herpetiformis,
alopecia areata, autoimmune cystitis, pemphigoid, scleroderma,
progressive systemic sclerosis, CREST syndrome (calcinosis, Raynaud's
esophageal dysmotility, sclerodactyly, and telangiectasia), adult onset
10 diabetes mellitus (Type II diabetes), male or female autoimmune
infertility, ankylosing spondylitis, ulcerative colitis, Crohn's disease,
mixed connective tissue disease, polyarteritis nodosa, systemic necrotizing
vasculitis, juvenile onset rheumatoid arthritis, glomerulonephritis, atopic
dermatitis, atopic rhinitis, Goodpasture's syndrome, Chagas' disease,
15 sarcoidosis, rheumatic fever, asthma, recurrent abortion, anti-phospholipid
syndrome, farmer's lung, erythema multiforme, postcardiotomy syndrome,
Cushing's syndrome, autoimmune chronic active hepatitis, bird-fancier's
lung, asthma, allergic disease, allergic encephalomyelitis, toxic
necrodermal lysis, alopecia, Alport's syndrome, alveolitis, allergic
20 alveolitis, fibrosing alveolitis, interstitial lung disease, erythema nodosum,
pyoderma gangrenosum, transfusion reaction, leprosy, malaria,
leishmaniasis, trypanosomiasis, chronic fatigue syndrome, fibromyalgia,
Takayasu's arteritis, Kawasaki's disease, polymyalgia rheumatica,
temporal arteritis, schistosomiasis, giant cell arteritis, ascariasis,
25 aspergillosis, Sampter's syndrome (triaditis also called, nasal polyps,
eosinophilia, and asthma), Behcet's disease, Caplan's syndrome, dengue,
encephalomyositis, endocarditis, myocarditis, endomyocardial fibrosis,
endophthalmitis, erythema elevatum et diutinum, psoriasis,
erythroblastosis fetalis, fascitis with eosinophilia, Shulman's syndrome,
30 Felty's syndrome, filariasis, cyclitis, chronic cyclitis, heterochromic
cyclitis, Fuch's cyclitis, IgA nephropathy, Henoch-Schonlein purpura,
glomerulonephritis, graft versus host disease, transplantation rejection,

-18-

cardiomyopathy, Alzheimer's disease, parvovirus infection, rubella virus infection, post vaccination syndromes, congenital rubella infection, Hodgkin's and non-Hodgkin's lymphoma, renal cell carcinoma, multiple myeloma, Eaton-Lambert syndrome, relapsing polychondritis, malignant 5 melanoma, cryoglobulinemia, hepatitis B virus infection, hepatitis C virus infection, Waldenstrom's macroglobulinemia, mumps virus infection, and any other disorder in which the specific recognition of the host by immunoglobulin, B cell surface receptor (surface immunoglobulin), or T cell receptor is suspected or shown to be important in any aspect of the 10 pathogenesis of the clinical illness.

Immunization is any procedure which leads to a cellular or humoral immune response directed against an identifiable and specific antigen, usually the immunogen. An antigen is a substance that is bound by antibody. Sometimes an antigen is also referred to when meaning a 15 substance against which any immune response is directed and that it may be bound by antibody or lead to a cellular immune response. An autoantigen means a constituent of self that binds antibody (making it an autoantibody) or that induces a cellular response, for example, by a T cell. The spliceosome is that molecular apparatus, composed of RNA and 20 protein, which splices heteronuclear RNA, thereby removing the introns from the coding sequence of RNA. The cellular response may be assayed by presentation of a peptide from the autoantigen, proliferation, cell activation, the prevention of cell activation, secretion of cytokines, activation of apoptosis, or other indication of an effect of the presence of 25 the autoantigen. An autoantibody is any immunoglobulin, antigen specific B cell surface receptor (surface immunoglobulin), or antigen specific T cell receptor directed against self protein. Such T cell receptors usually bind peptides which themselves are bound by histocompatibility molecules. The T cell receptor usually binds to both the peptide and the 30 histocompatibility molecule.

Therapy is a treatment by medical or physical means. A "treatment" is the composition used for treating a condition. Antiviral

-19-

therapy is the use of a treatment in an effort to suppress or eliminate a virus, for example, suppression, elimination or other amelioration of the effect of Epstein-Barr virus. Peptides are small proteins composed of amino acids covalently bound to one another by peptide bonds. Peptides 5 may be prepared by an *in vivo* mechanism, as in life, by using the nucleic acid encoding for the sequence of the peptide produced, or *in vitro* using peptide chemistry. A vaccine is a composition or preparation that is used in an attempt to prevent a disease or ameliorate a disease. A disease is any illness.

10 Seroconversion means that the subject has developed antibodies of sufficient magnitude in the serum to conclude that the subject has made an immune response against the agent or substance of interest. Usually, this is the result of immunization (vaccination) or infection. Seropositive means that there are a sufficient quantity of antibodies with sufficient 15 affinity to conclude that seroconversion has occurred. Seronegative means that the quantity and affinity of antibodies are not sufficient to conclude that seroconversion has occurred. In this application, the terms "lupus" and "systemic lupus erythematosus" are used interchangeably.

20 The single amino acid code is used in the figures and following examples, as follows:

A - alanine	I - isoleucine	R - arginine
C - cysteine	K - lysine	S - serine
D - aspartic acid	L - leucine	T - threonine
E - glutamic acid	M - methionine	V - valine
25 F - phenylalanine	N - asparagine	W - tryptophan
G - glycine	P - proline	Y - tyrosine
H - histidine	Q - glutamine	

Therapeutic and Diagnostic Compositions

Vaccines

30 Immunity against a viral infection can be induced using either peptides, viral proteins or other components of the virus such as

-20-

carbohydrate components, substances which imitate structures of the virus, or the virus. In the preferred embodiment, the vaccine is based on the viral proteins wherein the epitopes cross-reactive with the splicesomal proteins are deleted. In other embodiments, the vaccine is based on viral 5 proteins where epitopes cross-reactive with antibodies to other known autoantigens are deleted or altered to decrease their immunoreactivity with autoantibodies. In still other embodiments, the vaccine includes the virus, either live, modified or inactivated, or components thereof, in a vehicle which can be administered in a dosage form and over a schedule eliciting 10 a strong immune response to kill the virus, but which does not elicit an autoimmune response.

An unmodified vaccine may be useful in the prevention and treatment of autoimmune disease related to Epstein-Barr virus. The dose, schedule of doses and route of administration may be varied, whether 15 oral, nasal, vaginal, rectal, extraocular, intramuscular, intracutaneous, subcutaneous, or intravenous, to avoid autoimmunity and, yet, to achieve immunity from Epstein-Barr virus infection. The response to the unmodified vaccine may be further influenced by its composition. The particular adjuvant employed (its concentration, dose and physical state), 20 concentration of the virus in the vaccine, and treatment of the unmodified vaccine with physical environmental changes, for example, temperature and pressure, the particular buffer, and the particular preservative(s) (if any) will be selected to reduce the likelihood of developing an autoimmune disorder, for example using the animal strains discussed 25 below. This same or different vaccine may be useful in reducing or eliminating the effect of an existing latent or active Epstein-Barr virus infection upon autoimmunity.

Peptides of up to about forty amino acids, more preferably between four and twenty-five amino acids, most preferably eight amino 30 acids, can be synthesized using any one of the methods known to those skilled in the art. In general, an epitope of a protein is composed of between three or four and eight amino acids (see Watson et al., "Certain

-21-

Properties Make Substances Antigenic," in Molecular Biology of the Gene, Fourth Edition, page 836, paragraph 3, (The Benjamin/Cummings Publishing Company, Menlo Park, 1987). As used herein, the peptides can contain the entire native epitope, or portions thereof sufficient to react

5 with autoantibody.

Although described in the literature with reference to specific sequences encoding viral proteins or the autoantigens, a number of substitutions using natural or synthetic amino acids can be made in the peptides to yield an peptide acting as a linear epitope that is functionally

10 equivalent to the disclosed sequences, for example, as demonstrated by James and Harley, J. Immunology 148:2074-2079 (April 1992).

Accordingly, the term linear epitope as defined by a specific sequence is used herein to include peptides having substitutions yielding a peptide bound in an equivalent manner or extent by an antibody or autoantibody.

15 For example, using monoclonal antibodies against peptide determinants of Sm B/B', substitution studies demonstrated that A, G, and S can substitute for R in PPPGMRPP (SEQ ID NO:4) in the binding of one antibody, KSm3. Analogously, F, H, T, V and Y can substitute for I in PPPGIRGP (SEQ ID NO:5) in the binding of KSm3.

20 Solid phase binding of autoantibodies to peptides has proven useful for examining sequential linear epitopes, also referred to as "linear" or "sequential". These have been useful to define important residues in epitope structure. This approach may or may not be less useful in defining conformational epitopes or regions where two or more linear, but

25 not sequential, epitopes are brought together by the tertiary structure.

The particular structural relationships between the autoantigens and autoantibody with particular regard to the particular conformation assumed by the peptide determines what can be learned by this approach. In addition, although many peptides may assume conformations in

30 solution that are not found in the native protein structure, true epitopes may still be delineated by this method. Those peptides that tend to have a structure similar to that found in the native molecule are expected to

-22-

usually be bound by a larger proportion of the autoantibodies that bind the analogous sequence on the native protein and/or may be bound with greater affinity.

It is believed that naturally arising human lupus follows a progression similar to that induced in the rabbit model described in the examples. Using this model, an immune response to a peptide, one very similar to a region of EBNA-1, is the seminal, initiating event for the subsequent autoimmunity and disease manifestations of lupus, where they occur. A structure, such as a peptide, that is capable of inducing autoimmunity is not necessarily identical to the structure found in the autoantigen. Indeed, it is possible that these structures would commonly be at least slightly different, when comparing the substance that induces the autoimmune response and the analogous structure in the autoantigen. On the other hand, there must be a basis for the non-autoantigen substance to induce autoimmunity. This is best identified as a cross-reaction wherein the immune recognition molecule binds, though not necessarily equally, to both the non-autoantigen substance as well as to the autoantigen.

The proposed mechanism is as follows. An immune response against a non-autoantigenic substance occurs. Some fraction of the antibodies thereby produced recognize the autoantigen and hence are autoantibodies. These autoantibodies facilitate the processing and antigen presentation of the autoantigen via the B cell surface immunoglobulin which serve as receptors, in this case for autoantigen, or via immunoglobulin cell surface receptors that are found on a variety of cells capable of antigen presentation. Once this occurs the immune response expands to other structures of the autoantigen and a full-blown, complete autoimmune response against the autoantigen ensues, which can result in clinical illness.

Based on this mechanism, the autoimmune responses progress from one or a few initial antigenic structure(s) to a much more complex response focused upon the autoantigen. Elucidating the pattern of

-23-

progression and understanding the relationship of autoimmune serologic findings to clinical manifestations places the physician in a strong position to accurately prognosticate and prepare patients and their families for the more likely outcomes.

5 In the case of systemic lupus erythematosus and the anti-Sm response, one method is to repeat the assays determining autoantibody binding to peptides over time. The effect of the peptide *in vitro* on cells from patients can also be measured. Proliferation, secretion of cytokines, interferons and other substances, expression of cell surface molecules and 10 activation are typically useful diagnostic indicators.

15 This strategy to generate autoimmunity can also be used to develop reagents that are useful in diagnosis or treatment of autoimmune disorders. Animal antibodies that compete with or otherwise facilitate the identification of particular fine specificities of binding can be important in evaluating prognosis. Moreover, the peptide binding pattern to the 20 octapeptides from the nRNP A protein show two different patterns. It should be possible to correlate a particular pattern found in a patient to obtain an indication of the stage the disease currently is at as well as the clinical prognosis. Reagents developed as a consequence of immunizing animals with autoantigenic peptides could be used to identify these differences. Such reagents include antisera, T cell lines, subsets of 25 antibodies, individual antibodies, subsets of cells bearing a subset of the T cell receptors, individual T cell receptors, and cytokines and other substances elaborated by cells from the animal. The antibodies and T cell receptors are construed to include recombinant antibodies or T cell receptors derived from a peptide-immunized animal.

30 The RNA-protein particles which are the major autoantigens may now be purchased commercially. The reagents made available by the animal model of autoimmunity described herein will be useful in the manufacturing and testing of autoantigens. Affinity purification using animal antiserum (absorbed or otherwise prepared) could be used for purification of the naturally occurring autoantigens.

-24-

Having a mechanism of disease provides the opportunity to apply new strategies for prevention of disease and for specific immunologic correction of the immune abnormalities that lead to disease, and therefore more accurately design the therapy.

5 For example, with the realization that the generation of autoimmune disease can be divided into phases comes the appreciation that the therapeutic opportunities will be similarly partitioned. As a specific example, the influence of vaccination with an analog of PPPGMRPP (SEQ ID NO:4) will be different depending not only upon

10 the structure of the immunogen, but also upon the pharmaceutical carrier, upon the maturity of the autoimmune response against PPPGMRPP (SEQ ID NO:4) and Sm, and upon other therapeutics that may be administered concomitantly. Such therapeutics include drugs as well as biologics, such as cytokines, immunoglobulins, and interferons, among others.

15 As a second specific example, mice strains exist which produce lupus autoimmunity, as well as strains which do not produce lupus autoimmunity, after immunization with PPPGMRPP-MAPTM (SEQ ID NO:4). The genetic, biochemical, and physiological differences between these strains can be used to develop diagnostics, including genetic markers

20 and risk factors, and therapeutics for autoimmune disease, especially lupus, using techniques known to those skilled in the art.

As discussed above, based on the data confirming that Epstein-Barr virus is an inducing agent for lupus, it is possible to design therapeutics to prevent or inhibit further progression of lupus by

25 vaccinating with Epstein-Barr virus, or components thereof, using standard vaccination procedures, most preferably after alteration or removal or masking of the sites which elicit the autoimmunity.

The peptides can be used therapeutically in combination with a pharmaceutically acceptable carrier. The peptides can be administered in

30 a dosage effective to block autoantibodies or as a vaccine to block the production of autoantibodies, by eliciting a protective immune response against non-autoantigenic regions of the pathogen. The peptide acts as a

-25-

functional antagonist by binding to antibody that does not stimulate or activate the immune cells and thereby block the immune response to the autoantigens.

Pharmaceutical carriers are known to those skilled in the art.

5 These most typically would be standard carriers for administration of vaccines to humans, including solutions such as sterile water, saline, and buffered solutions at physiological pH. Peptides used as vaccines are most preferably administered intramuscularly or subcutaneously. Other compounds will be administered according to standard procedures used by
10 those skilled in the art.

Alternatively, the peptides used for treatment might include peptides homologous to an identified antigenic sequence. These peptides, either free or bound to a carrier, could be delivered to a patient in order to decrease the amount of circulating antibody with a particular

15 specificity. In addition, knowledge of the cross-reacting epitopes between a foreign antigen and an autoantigen may allow for re-induction of tolerance. It is well known in experimental models of the immune response that the response can be suppressed and tolerance induced by treatment with the antigen. Peptide therapy with the cross-reacting sequences may be a useful therapy in autoimmune diseases.

20

The amino acid sequences can also be used to make agents for neutralizing circulating antibodies or immobilized on substrates in extracorporeal devices for specific removal of autoantibodies, using methodology known to those skilled in the art.

25 *Diagnostics*

Individuals who are not at as great a risk for developing autoimmune disease can be identified by reactivity to the various peptides, for example, as demonstrated in the examples where individuals who are not prone to develop lupus are characterized by antibodies to GAGAGAGAGAGAGAGAGAGAGAGAGA (SEQ ID NO: 7). Other structures derived from Epstein-Barr virus can be used to predict who will develop autoimmune disease. For example,

-26-

GAGAGAGAGAGAGAGAGAGAGAGAGAGA (SEQ ID NO:7) is a commonly identified antigen from Eptein-Barr virus in normal individuals, while lupus patients do not tend to bind this structure. An individual identified at risk for the development of an autoimmune disease, but who does not 5 yet manifest autoimmunity or symptoms of the disease, may require a special therapeutic approach. This is an opportunity to induce immune suppression before the process leading to autoimmune disease is initiated. Strategies such as intravenous administration of large amount of the initiating structure is known to induce tolerance. Small sub-immunogenic 10 doses of the initial immunogen can also be used to induce tolerance.

There is a limited opportunity to interrupt or redirect an immune response that has been initiated against the first components of the autoantigen. Here again the induction of suppression by the use of the component peptides or analogs thereof with or without concomitant drugs 15 or biologics has the potential to inhibit progression into an autoimmune disorder. Once autoimmunity against the autoantigen is established, the use of component peptides or their analogs with or without concomitant drugs or biologics may interrupt the course of the autoimmune response, thereby ameliorating the illness.

20 The animal model provides an opportunity to optimize ways of interrupting and reversing the autoimmune process. For example, it has been observed that one of the rabbits immunized with Map-PPPGMRPP (SEQ ID NO:4) seemed to improve clinically somewhat after developing the most severe manifestations of systemic autoimmunity. If this result is 25 the effect of a particular antibody, then this antibody may have the capacity to influence the maturation of the immune response toward alleviating the disease in other species. For example, such an antibody could be isolated by biochemical methods, by recombinant DNA methods or by hybridoma monoclonal methods, humanized using standard 30 technology and then administered to patients as a specific therapeutic agent for disease. T cell receptors or cytokines could be equally useful.

Assays

Subsets of antigenic peptides have the potential to identify patients at risk for particular clinical manifestations or patients in particular prognostic groups. The peptides can be used in combination in assays, 5 such as the solid phase assay, to classify patients.

Specifically, the peptides that are bound by autoantibodies in patients characterized by specific disorders, such as renal disease or central nervous system involvement, are selected and combined in an assay, such as an ELISA for a test to detect the collection autoantibodies 10 that bind this particular collection of peptides. Using a mixture of peptides may increase the efficiency and reliability of such assays, as compared with using a single autoantigen, or a single peptide.

The peptides can be used in solution or immobilized to a solid substrate, such as a gel suitable for affinity chromatography, or a multi-well plate, using standard techniques such as the commercially available 15 cyanogen bromide.

The present invention will be further understood by reference to the following non-limiting examples.

Example 1: The relationship of anti-Sm to Epstein-Barr virus.

20 The anti-Sm and anti-nuclear ribonucleoprotein (nRNP) autoantibody specificities have an Ouchterlony precipitin reaction of partial identity. This is because the epitopes bound are found on two antigens which share some, but not all antigenic features. The Sm autoantigen may be found in association with the U1, U2, U5 or U4/6 25 spliceosomal particles. These are composed of specific U RNA and particular peptides. The nRNP autoantigen is composed of only U1 RNA and particular unique peptides. The anti-Sm antibodies bind to the B/B' or D spliceosomal peptides in Western blot while the anti-nRNP autoantibodies bind 70K, A or C peptides (Lerner, M.R. and Steitz, J.A. 30 Proc. Natl. Acad. Sci. USA 76:5495-5499 (1979); Hinterberger, M. J. Biol. Chem. 258:2604-2613 (1983); and Petterson, I. et al. J. Biol. Chem. 259:5907-5914 (1984)). (B/B' and D are found in the U1, U2, U5

-28-

and U4/6 spliceosomal particles. A protein termed the N protein or the Sm N protein is closely related to B and B'. 70K, A and C are usually only found in U1.) Anti-Sm precipitins are found in about 10% to 20% of lupus patients. Anti-Sm is sufficiently specific for this diagnosis that 5 its presence in the serum has become part of the 1982 Criteria for the Classification of Systemic Lupus Erythematosus (Tan E.M., et al Arthritis Rheum. 25:1271-1277 (1982)).

10 *Antigenicity of B/B' peptides assessed by measuring antibodies binding to octapeptides synthesized in vitro from the sequence of the B/B' Sm peptide.*

15 The autoantigenicity of Ro (also known as the SS-A) autoantigen was reported by Scofield, R.H. et al. Proc. Natl. Acad. Sci. USA 81:3343-3347 (1991). The antigenicity of the B/B' peptides was assessed by measuring antibodies binding to octapeptides synthesized *in vitro* from 20 the sequence of the B/B' Sm peptide, as described by James, J.A. and Harley, J.B. J. Immunol. 148:2074-2079 (1992). Representative data from an anti-Sm precipitin positive patient are shown in Figure 1D and controls in Figures A-C. Note that eleven groups of peptides are bound by the sera containing anti-Sm autoantibody. One of the most unexpected 25 observation was that all of the anti-Sm sera tested bound almost the identical octapeptide structures (Figure 2).

25 The sequence PPPGMRPP (SEQ ID NO:4) is repeated three times in Sm B' (Van Dam, A. et al. EMBO J. 8:3853-60 (1989)). The N protein, which is very homologous to the B/B' protein, has three repeats of PPPGMRPP (SEQ ID NO:4) and a closely related sequence PPPGIRGP (SEQ ID NO:5) is also found once (Schmauss C. et al. Nuc. Acid Res. 17:1733-43 (1989)). PPPGIRGP (SEQ ID NO:5) is not found in the B' protein ; rather, PPPGMRGP (SEQ ID NO:8) is found in its place. Much confusion has surrounded this area due to the original 30 publication of the Sm B/B' sequence (Rokeach L.A. et al. J. Biol. Chem. 264:5024-30 (1989); Sharpe N.G. et al. FEBS Lett. 250:585-90 (1989)) which was later found to actually produce what is now termed the N protein or the Sm N protein (Schmauss C. et al. Nuc. Acid Res. 17:1733-

-29-

43 (1989)). Lupus patients with anti-Sm precipitins all have antibodies which bind to both Sm B (a truncated version of Sm B'), Sm B' and Sm N. Substantial cross-reactivity occurs between the three proteins.

Such repeated structures are sometimes particularly immunogenic.

5 These anti-Sm sera also bind to some of the known sequences which are structurally similar to PPPGMRPP (Figure 3 SEQ ID NO:4). These sequences included PPPGRRP (SEQ ID NO:1), which is found in the Epstein-Barr Nuclear Antigen-1 (EBNA-1) protein. GRGRGRGG (SEQ ID NO:2) and RGRGREK (SEQ ID NO:3) are also sequences from 10 Epstein-Barr virus Nuclear Antigen-1, but these are similar to a major antigenic epitope of Sm D in lupus patients, GRGRGRGRGRGRGRGRGGPRRR (SEQ ID NO:9) (James, J.A., et al. Clin. Exp. Immunol. 98:41-426 (1994)). (See GenBank accession code: gb-vi.ebv for sequences of Epstein-Barr virus proteins.) All three 15 peptides appear to bind at least three times more antibody from the anti-Sm precipitin positive lupus patient sera than the controls. The antibody binding to these peptides in the lupus patient sera was over half of the antibody binding level found for PPPGMRPP (SEQ ID NO:4).

20 *Serum samples from lupus patients stored early in the course of the disease process bind only PPPGMRPP (SEQ ID NO:4) (and neighboring peptides) of the 233 possible octapeptides of B/B'*

The analysis of stored sera revealed that a serum sample from an lupus patient stored early in the course of her disease process bound only PPPGMRPP (SEQ ID NO:4) (and neighboring peptides) of 25 the 233 possible octapeptides of B/B' (Figure 4) (James, J.A. et al. J. Exp. Med. 181:453-461 (December 1995)). This repeated PPPGMRPP (SEQ ID NO:4) motif is an early target in three additional patients tested from whom sera were available from early in their disease. In all of these patients PPPGMRPP (SEQ ID NO:4) is the first autoimmune 30 epitope of the Sm B/B' autoantigen against which one can detect antibody binding. One interpretation of this finding is that PPPGMRPP (SEQ ID NO:4) is the first structure bound in at least some of those lupus patients who have anti-Sm autoantibodies. Most, if not nearly all, sera with anti-

-30-

Sm have more complex binding when they present to their doctors with the illness. At this point no anti-Sm precipitin positive lupus patient who does not have antibodies to PPPGMRPP (SEQ ID NO:4) is known.

Antibodies directed against PPPGMRPP (SEQ ID NO:4) are a significant portion of the anti-Sm response in some patient sera. Five patient sera have been absorbed over columns composed of PPPGMRPP (SEQ ID NO:4). Four of these sera had anti-Sm and anti-nRNP precipitins and one had an anti-nRNP precipitin without anti-Sm; all five had anti-Ro autoantibodies which were above the normal range. The PPPGMRPP (SEQ ID NO:4) absorption removed 13 to 39% of the patient anti-Sm/nRNP response. These same column absorptions removed less than 10% of the anti-Ro reactivity and over 95% of the anti-PPPGMRPP (SEQ ID NO:4) response. (The proportion of the anti-Sm/nRNP activity absorbed varies with the number of the other octapeptides from Sm B/B' and D proteins bound by immune serum being tested.)

Rabbits immunized with PPPGMRPP (SEQ ID NO:4) developed antibody beyond the peptide of immunization which bound to many other octapeptides in the spliceosome, antinuclear autoantibodies, anti-double stranded DNA autoantibodies and clinical features that suggests the illness known in man as systemic lupus erythematosus

Rabbits were immunized with PPPGMRPP (SEQ ID NO:4) on a MAPTM backbone (referred to as PPPGMRPP-MAPTM (SEQ ID NO:4) where the trademark refers only to the MAPTM). These animals developed antibody beyond the peptide of immunization which bound to many other octapeptides in the spliceosome. These rabbits usually developed anti-PPPGMRPP (SEQ ID NO:4) antibodies along with anti-Sm and anti-nRNP autoantibodies, antinuclear autoantibodies, anti-double stranded DNA autoantibodies and clinical features that suggests the illness known in man as systemic lupus erythematosus. These rabbits variably had seizures, thrombocytopenia, proteinuria, renal insufficiency, cellular casts in the urine, hypoalbuminemia and alopecia (James, J.A. et al. J. Exp. Med. 181:453-461 (1995)). This has led to a new model of

-31-

autoimmunity and suggests that a vigorous immune response against this one sequence, PPPGMRPP (SEQ ID NO:4), is sufficient to induce a specific autoimmune disease in some strains of animals.

PPPGRRP (SEQ ID NO:4) from the Epstein-Barr virus Nuclear
5 Antigen-1 was found when the sequence was searched for sequences similar to PPPGMRPP (SEQ ID NO:4). To preliminarily test whether it was possible for this sequence to induce spliceosomal autoimmunity, two rabbits were immunized with PPPGRRP-MAP™ (SEQ ID NO:1) following the protocol previously used with PPPGMRPP-MAP™ (SEQ ID
10 NO:4). One of the two rabbits developed not only anti-PPPGMRPP (SEQ ID NO:4) antibodies, but also anti-spliceosomal autoantibodies and had B cell epitope spreading to regions of B/B' and D, as evidenced by antibody binding to other octapeptides (Figures 5 and 6).

If a structure from a virus could induce anti-spliceosomal
15 autoantibodies when immunized in an animal then, this is evidence that this structure and the virus is important in the induction of the autoimmune disease associated with anti-spliceosomal autoantibodies, systemic lupus erythematosus.

These data suggest a sequence of events, as follows: infection with
20 Epstein-Barr virus, development of anti-PPPGRRP (SEQ ID NO:1) antibodies, development of surface immunoglobulin (and secreted antibody) binding both PPPGRRP (SEQ ID NO:1) and PPPGMRPP (SEQ ID NO:4) (the first evidence of autoimmunity), antigen processing of the spliceosome bound by surface immunoglobulin (or soluble antibody) and
25 presentation of the spliceosomal peptides, B cell epitope spreading (and perhaps T cell epitope spreading) and clinical features of lupus. Epstein-Barr virus infected cells are believed to encourage this sequence of events at a number of steps. By substituting another antigen for PPPGRRP (SEQ ID NO:1) and another autoantigen for PPPGMRPP, (SEQ ID
30 NO:4) this mechanism may generate lupus or another autoimmune disorder by following the same general sequence of events.

-32-

Genetic Linkages in Mice to Development of Lupus-like Autoimmunity After Immunization with PPPGMRPP-MAPTM (SEQ ID NO:4)

Experiments in mice have shown that there are some strains which

5 develop lupus-like autoimmunity after immunization with PPPGMRPP-MAPTM (SEQ ID NO:4) and some that do not (J.A. James et al. Arthritis Rheum. 38:S226 (1995)). The difference between one responder (develops lupus-like autoimmunity) and one nonresponder mouse strain has been preliminarily localized to a region on mouse chromosome 4

10 (James, J.A. and Harley, J.B. Arthritis Rheum. 39:S216 (1996)).

This preliminary finding of linkage in this murine model of lupus suggest that the difference between the two parent strains of a recombinant inbred set of mice which determines the observable B cell epitope spreading and autoimmunity may be found at a single gene locus.

15 This region of murine chromosome 4 does not contain immunoglobulin genes, T cell receptor genes, nor the histocompatibility genes which are highly variable polymorphic genes which determine so many other features of the immune response. The gene for CD72 is found here which may be important. Once the gene responsible for the observed

20 effect is identified, then one skilled in the art can provide compositions for diagnosis, prevention and treatment of autoimmune disease. Beyond this specific example, it is expected that other genes and gene products will be shown to be important and analogous compositions will be obvious to one skilled in the art.

25 The host experiences changes after Epstein-Barr virus infection beyond the generation of an immune response. Gene expression and molecular machinery in infected cells is altered by the virus. These changes can be detected by those skilled in the art and used as diagnostics, as well as in the screening and development of therapeutics

30 which are particularly important for individuals affected with or at risk of becoming affected with autoimmune disease.

Example 2. Association of seroconversion against Epstein-Barr virus and an autoimmune disease.

Sera from lupus patients compared with controls were first tested for seroconversion against Epstein-Barr virus. There were a number of 5 important considerations in designing these experiments. First, the older and more traditional assays for Epstein-Barr seroconversion were insufficiently specific. These assays are especially unreliable when applied to sera from lupus patients. Antinuclear autoantibodies in lupus sera often interfere with the test for Epstein-Barr seroconversion when an 10 Epstein-Barr virus-infected cell line is used for the test. Both a positive test result for Epstein-Barr virus and for antinuclear antibodies involving the nuclear fluorescence of the cell line. Also, the infected cell line test for Epstein-Barr virus is often not positive in people known to have been infected with Epstein-Barr virus. Others have used such assays in patients 15 with systemic lupus erythematosus with disappointing results (Tsai, Y. et al. Int. Arch. Allergy Immunol. 106:235-240 (1995)).

Second, in the United States as many as 95% of normal adults are infected with and have evidence of seroconversion against Epstein-Barr virus (Evans, A.S. and Niederman, J.C.: Epstein-Barr virus. In Viral 20 Infections in Humans, 3rd ed. Evans, A.S. ed. pp 265-292 (Plenum, New York City 1989)). To detect a difference in adults above the 95% expected baseline of Epstein-Barr virus infection with confidence would require an unreasonably large number of patients and controls. On the other hand, in the United States, most people contract Epstein-Barr virus 25 before the age of 20 years. Epstein-Barr virus causes infectious mononucleosis, also known as the "kissing disease", in some people. Controls who are children and adolescents will have a lower rate of infection than individuals who are older. By using younger patients and controls, it was thought that one might be able to collect a group of 30 controls where the rate of Epstein-Barr virus seroconversion is less, perhaps less than 75%, thereby a sufficient increase in statistical power to enable this question to be addressed with the resources available.

-34-

The use of children and adolescents has nothing to do with anything unique or different about lupus in childhood or adolescence compared with the disease in adults. Rather, the younger cases represent the population in which the hypothesis of a relationship between Epstein-Barr virus infection and autoimmune disease can be most efficiently tested.

5 The most reliable test for seroconversion is against the Viral Capsid Antigen of Epstein-Barr virus, also called gp340/220 (and abbreviated as EBV-VCA). Solid phase assays are available for antibodies 10 against this surface protein. The purification methods may include other proteins and antigens from Epstein-Barr virus, but as long as a substantial proportion of the preparation is composed of this surface antigen of Epstein-Barr virus, then the assay should be sensitive for an immune response directed against Epstein-Barr virus. The procedure used to 15 isolate the antigen used in the commercial ELISA (enzyme-linked immunosorbent assay) kits has been described in detail (Qualtiere, L.F. and Pearson, G.R. Virology 102:360-369 (1980)). Antibodies binding to the Epstein-Barr virus surface protein are thought to occur in virtually everyone who is infected with Epstein-Barr virus. An assay for 20 antibodies binding to the Epstein-Barr virus Viral Capsid Antigen (EBV-VCA) is marketed by only two manufacturers in the United States. The assay first used was manufactured by Clark Laboratories, Inc. (Jamestown, New York). This firm was recently acquired by Wampole Laboratories, a division of Carter-Wallace, Inc. (Cranbury, New Jersey) 25 who has continued to provide the same viral assays. The manufacturer's instructions were followed in measuring the anti-VCA Epstein-Barr virus IgG antibodies in lupus patients and their controls, all of whom tested are under 20 years old.

The results are striking. Of the 134 tested sera from controls, 96 30 have IgG antibodies that bind at a sufficient level to conclude that these individuals have seroconverted. The sera from the lupus patients in this

-35-

experiment are nearly all seropositive at 102 of 103 or over 99% (Table 1).

Table 1. Seroconversion frequencies in pediatric lupus and controls for IgG binding to Epstein Barr virus viral capsid antigen (EBV-VCA).

**Anti-Epstein-Barr virus Viral Capsid Antigen IgG
(# seroconverted (total tested))**

Oklahoma cases and controls

Lupus cases	45(45)
Controls	53(76)
Odds ratio	38
χ^2	15.1
p	<0.0001

San Diego and New York City cases and controls

Lupus cases	57(58)
Controls	43(58)
Odds ratio	20
χ^2	14.1
p	<0.001

Combined data from lupus cases and controls

Lupus cases	102(103)
Controls	96(134)
Odds ratio	40.4
χ^2	31.6
p	<0.00000001

Odds ratios were calculated from the contingency tables. A χ^2 test was used to assess significance. The assays for all viral antigens were obtained from Clark Laboratories (Jamestown, NY) now a division of Wampole Laboratories (Cranberry, New Jersey) and were performed

-36-

according to the instructions provided by the manufacturer. The surface antigen is partially purified for the anti-Epstein-Barr virus Viral Capsid Antigen antibody assay (Qualtiere, L.F. and Pearson, G.R. *Virology* 102:360-369 (1980)).

The quantitative level of binding to the Epstein-Barr virus Viral Capsid Antigen (as measured relative to the standardized calibrator and as recommended by the manufacturer) also show substantial quantitative differences between lupus cases and controls (Table 2).

Table 2. Binding of IgG in sera from pediatric lupus patients and their controls to the Viral Capsid Antigen from Epstein Barr virus (EBV).

**Epstein-Barr virus Viral Capsid Antigen
(International Standardized Ratios (ISRs))**

Lupus cases (n=103) (ISRs)	4.368
Controls (n=134)(ISRs)	2.087
t-test	14.82
probability (p value)	<<0.001

Assay is performed as presented in Table 1. Data are presented as International-Standardized-Ratios-(ISRs)-which-are-calculated-as described by the manufacturer. The average binding of each tested serum is divided by the product of the calibrator and a lot-specific factor. This allows for standardization across assays. Values <0.9 are considered negative and values >1.1 are considered positive. Values between 0.9 and 1.1 are equivocal and are either retested or are assigned to the not positive or negative group. (No patient serum tested to date has had a result in this equivocal range.)

If the suspected relationship between systemic lupus erythematosus held only for the lupus patients who were anti-Sm positive, then the proportion of lupus patients who had developed the anti-Epstein-Barr virus surface molecule (gp340/220) antibody would be increased over controls

-37-

only modestly, since the proportion of lupus patients with anti-Sm in their sera rarely exceeds 30%. The remaining lupus patients would have been expected to have the normal control frequency of Epstein-Barr virus seroconversion.

5 Patients with lupus have such different clinical manifestations from patient to patient, that many investigators suspect that there are many different causes of this disease. Any given particular etiology causing lupus would then be expected to account for only a proportion of the cases. For example, assume that lupus, as observed in the clinics,
10 happens to have two different origins, one from a virus such as Epstein-Barr virus and another from the intrinsic genetic program of some patients. Further assume that the Epstein-Barr virus only accounts for the individual patients who have anti-Sm or anti-nRNP autoantibodies and that this is half of the lupus patients (which is approximately true). Under this
15 scenario, one would expect to see a statistical effect of increased Epstein-Barr virus infection in the group of lupus patients, as a whole, when compared to controls, but the effect would be driven by only half of the patients. Consequently, the proportion of lupus patients with evidence of Epstein-Barr virus infection would be raised, from 71% to 85.5%, but not
20 to the 99% level that has been observed. This 99% rate is the level that would be expected if over 95% of the lupus cases in the collection have been caused by Epstein-Barr virus.

The association is consistent with Epstein-Barr virus infection being a necessary condition before this autoimmune disease can develop
25 in nearly all lupus patients. Assuming Epstein-Barr virus accounts for nearly all cases of lupus, as suggested by the data, then this virus is capable of mediating the various autoimmune manifestations found in lupus beyond just the relationship with anti-Sm antigen originally postulated. Autoantigens in lupus patients are generally thought to be
30 found throughout the tissues of the host and not to be restricted to a single tissue. This is true for Sm, nRNP, Ro, La, P, DNA, and RNA, among many other autoantigens in lupus. Some patients may have antibodies

-38-

binding other autoantigens which are tissue specific, such as thyroglobulin, but these seem to be less important in this disease.

Virtually all active lupus patients have a positive antinuclear antibody, suggesting that at least one of the autoantigens bound by patient

5 autoantibody is directed against a cellular constituent shared between tissues.

This mechanism already allows for a large number of autoantigens. If all of these autoimmune manifestations are related to Epstein-Barr virus infection, then it is probable that other autoimmune disorders are related

10 also. Only a change in the location of the antigen in the host would be required to generate another disorder, among other mechanisms, for Epstein-Barr virus to be a necessary, but not sufficient condition for the development of other autoimmune diseases. For example, a similar mechanism could operate for thyroglobulin or thyroid peroxidase, leading

15 to a tissue specific autoimmune disorder, autoimmune thyroid disease.

Again Epstein-Barr virus infection would be a requirement before most patients could develop the disease.

Interestingly, autoimmune thyroid disease and lupus sometimes coexist in the same patient. There are those who have suspected that

20 there is a relationship between systemic lupus erythematosus and autoimmune thyroid disease (R. H. Scofield Clin. Exp. Rheum. 14:321-

330 (1996)). Under these circumstances, Epstein-Barr virus could be fundamental to both disorders. Other features of the environment, virus strain differences, genetics of the host, hormone and cytokine status,

25 recent and remote immune history, and the nature and course of infection of the Epstein-Barr virus in the host, among other variables, probably then determine how the autoimmunity, as a consequence of Epstein-Barr virus infection, finds expression.

-39-

Example 3. Experiments to evaluate trivial and artifactual explanations for the association of Epstein-Barr virus serologic positivity with an autoimmune disease related to the source of the test for anti-Epstein-Barr Viral Capsid Antigen IgG antibodies.

5 Perhaps the association observed is explained by some artefact of the manufacturing process. Since there are two manufacturers who separately prepare the Viral Capsid Antigen and who use somewhat different procedures, a subset of the lupus patients and controls were 10 evaluated using the test manufactured by Gull Laboratories (Salt Lake City, Utah).

The results from the Gull test for Epstein-Barr seropositivity were virtually identical to those obtained with tests manufactured by Clark Laboratories, Inc. Of the 43 patient sera tested, all were positive for 15 Epstein-Barr virus IgG antibodies who were positive by the Clark assay. The one patient without antibodies to Epstein-Barr virus Viral Capsid Antigen by the Clark assay also had no detectable antibodies to Epstein-Barr virus Viral Capsid Antigen by the Gull assay. Of the 47 control sera tested, none were negative that were previously positive and four were 20 positive in the Gull anti-Epstein-Barr virus Viral Capsid Antigen assay that were previously negative.

This experiment established that the results in Example 1 were not explained by lot variation or an unusual property of the preparation used to detect anti-Epstein-Barr virus surface antigen.

25 **Example 4. Experiments to evaluate trivial and artifactual explanations for the association of Epstein-Barr virus serologic positivity with an autoimmune disease related to cross-reactivity of autoantibodies with anti-Epstein-Barr surface antigen IgG antibodies.**

30 Next, five of the lupus patients with high levels of anti-Sm autoantibodies were arbitrarily selected. The anti-spliceosomal autoantibodies were absorbed from their sera and their antinuclear

-40-

antibody titer reevaluated by immunofluorescence, and anti-Sm/nRNP and anti-Ro antibodies by solid phase assay (following previous methods (Gaither, K.K. et al. J. Clin. Invest. 79:841-846 (1987); Harley, J.B. et al. Arthritis Rheum. 29:196-206 (1986)), and anti-Epstein-Barr virus

5 **Viral Capsid Antigen IgG antibodies.**

The spliceosomal antigen preparation is affinity purified from bovine tissue and contains both the Sm and nRNP specificities and, hence, is referred to as Sm/nRNP. This is the same preparation discussed herein for solid phase assays against Sm/nRNP. The previous method for the 10 solid phase anti-Sm/nRNP assay (Gaither, K.K. et al. J. Clin. Invest. 79:841-846 (1987); Harley, J.B. et al. Arthritis Rheum. 29:196-206 (1986)) was altered by omitting inhibition with purified Sm/nRNP antigen. The same alteration was made in the anti-Ro assay.

These data show that the anti-Sm was reduced by at least 90% in each serum, as expected. In addition, the antinuclear antibodies were reduced by an average of 97%. Meanwhile, neither the anti-Ro nor the anti-Epstein-Barr virus surface antigen IgG antibodies were substantially reduced. The anti-Epstein-Barr virus surface antigen IgG antibodies were reduced by an average of 8%.

15 These data show that neither anti-Ro nor anti-Epstein-Barr virus
20 **Viral Capsid Antigen IgG** cross-reacts to any significant extent with the anti-Sm. If they had, then these antibodies would also have been removed by the absorption. In addition, the reduction of the antinuclear antibodies in the absorbed sera by 97% suggests that the anti-Sm/nRNP is 25 the major autoantigen in these lupus patients.

Example 5. Experiments to evaluate trivial and artifactual explanations for the association of Epstein-Barr virus serologic positivity with an autoimmune disease related a general polyclonality of autoantibodies in lupus sera.

30 It was possible that lupus sera may nonspecifically bind to any viral antigen. To test this possibility, the same patient and control sera were evaluated for antibodies against four other Herpes viruses:

-41-

Cytomegalovirus; Herpes simplex, type 1; Herpes simplex, Type 2; and
Varicella zoster (Table 3).

Table 3. Seroconversion frequencies in pediatric lupus and controls for IgG binding to cytomegalovirus antigen (CMV), Herpes simplex type 1 antigen (HSV-1), Herpes simplex virus type 2 antigen (HSV-2), and varicella zoster virus (VZV) antigens.

	CMV	HSV-1	HSV-2	VZV
<u>Oklahoma</u>				
Lupus cases	20(45)	30(45)	21(45)	42(45)
Controls	21(76)	32(76)	22(76)	71(76)
Odds ratio	2.1	2.75	2.14	0.99
χ^2	3.57	6.82	3.84	0.0
p	>0.05	<0.01	0.05	0.99

-42-

San Diego and New York City

Lupus cases	18(58)	33(58)	32(58)	46(58)
Controls	12(57)	31(57)	23(57)	45(57)
Odds ratio	1.69	1.11	1.82	1.02
χ^2	1.49	0.73	2.53	0.0
p	0.22	0.79	0.11	0.96

The odds ratios were calculated from the contingency tables. A χ^2 test was used to assess significance. The assays for all viral antigens were obtained from Clark Laboratories (Jamestown, NY) now a division of Wampole Laboratories (Cranberry, New Jersey) and were performed according to the instructions provided by the manufacturer. Whole inactivated virus is used for the CMV, HSV-1, HSV-2 and VZV antibody assays.

There is no consistent difference (at the level of $p < 0.05$) between the controls and the lupus patients for the frequency of seroconversion against any of the viruses tested except for Epstein-Barr virus. There is a small and significant difference between the cases and controls for IgG

5 autoantibodies against herpes simplex, Types 1 and 2 in the Oklahoma group (Table 3). Its inconsistency is typical of the results of other assays for seroconversion rates in lupus. Of these, only the difference between cases and controls for antibodies against Herpes Simplex virus Type 2 is significant across the entire collection, odds ratio is 2.07 ($\chi^2 = 7.39$,

10 $p = 0.006$). The low, but significant, odds ratio, suggests that the contribution of this virus is likely to be small. Some of the social behaviors that increase the risk of infection with Epstein-Barr virus probably secondarily also increase the risk of contracting Herpes Simplex virus, Type 2.

15 The modestly, and usually insignificantly, increased odds ratios for the seroprevalence of cytomegalovirus and Herpes simplex Types 1 and 2 in lupus patients compared to controls may reflect the increased levels of binding of antibodies found in other studies (Hollinger, F.B. et al. Bact. Proc. 131:174 (1970); Phillips, P.E. and Christian, C.L. Science

20 168:982-4 (1970); Hurd, E.R. et al. Arthritis Rheum. 13:724-33 (1970)).

-43-

In conclusion, these control assays do not support the position that the difference in the seroconversion rate between lupus patients and their collected controls is the result of a nonspecific binding to viral antigens.

Example 6. Experiments to evaluate trivial and artifactual explanations for the association of Epstein-Barr virus serologic positivity with an autoimmune disease related to hypergammaglobulinemia in the sera of patients with autoimmune disease.

To determine whether hypergammaglobulinemia might explain the differences observed, the IgG level in 32 of the lupus patients was assayed and compared this with the level found in 25 controls. No significant difference was found. In addition, no correlation was found between the IgG level and positive Epstein-Barr virus Viral Capsid Antigen assays. Therefore, an increased level of IgG binding non-specifically to the Epstein-Barr virus Viral Capsid Antigen cannot be an explanation for the findings.

Example 7. Demonstration of an increased rate of Epstein-Barr virus infection in systemic lupus erythematosus.

An assay for Epstein-Barr virus infection that is not dependent upon serologic analysis removes all of the technical reservations concerning possible artefact or a trivial explanation for the observed association between seroconversion against Epstein-Barr virus Viral Capsid Antigen and an autoimmune disease. To assay for Epstein-Barr virus, independent of serology, a method altered from the DNA based assays already available was developed. The *Bam*HI W repeat nucleic acid sequence of the Epstein-Barr virus genome contains a sequence repeated 11 times that others have used to detect the virus (Saito et al., J. Exp. Med. 169:2191-2198, 1989; and Miyashita et al., Cell 80:593-601, 1995). These assays were evaluated in an effort to increase specificity.

Two mcg DNA specimens were isolated from peripheral blood mononuclear cells. Quantitation of DNA was based both upon optical density measurements at 240 and 260 nm and quantitation of ethidium

-44-

bromide fluorescence in agarose gel relative to known DNA standards.

Where available, six reactions, each containing 2 mcg of mononuclear cell DNA, were evaluated from each subject. The primers and the probe used are given in Table 4.

Table 4. Primers and probe used to expand Epstein-Barr virus DNA from the *Bam*HI W repeat.

Forward - 5'-CCAGAGGTAAAGTGGACTT-3' (SEQ ID NO:10)

Reverse - 5'-GACCGGTGCCTCTTAGG-3' (SEQ ID NO:11)

Probe - 5'-AAGACGATTGGGTG(TGAGGTGGTGTGGGTCCGTGTGATGTGT-GTGGGTGGGCAG)-3' (SEQ ID NO:12)

* The ^{32}P -dCTP label is incorporated into the portion of the sequence in parentheses.

The polymerase chain reaction for each DNA specimen was run in a final volume of 75 μl with 50 mM KCl, 10 mM Tris-HCl at pH 8.0, 1.5 mM MgCl_2 , 0.1% Triton X-100, 0.2 mM each dNTP, 0.5 μM primer, and 2.5 U *Taq* DNA polymerase. A hot start protocol was followed using Ampliwx PCR GemsTM (Perkin-Elmer, Branchburg, N.J.). The thermocycler was programmed for the following temperature cycles: (95°C for 2 min, 57°C for 1 min, 72°C for 1 min) twice, (94°C for 1 min, 55°C for 1 min, 72°C for 45 sec) 31 times, 72°C for 5 min.

The primers variably expanded four bands found at

10 approximately 92, 122, ~500, and ~700 base pairs. All four were cloned into the pCRII vector (Invitrogen, San Diego, California) and at least partially sequenced. The 92, ~500, and ~700 base pair products of the polymerase chain reaction are not in the GeneBank database. They are likely to represent human sequence from a region of the genome that has 15 not yet been sequenced.

The 122 base pair product was similarly cloned and sequenced. The sequence obtained exactly matched the sequence predicted from the Epstein-Barr virus *Bam*HI W repeat, which is repeated 11 times and found at positions 14614-14735, 17686-17807, 20758-20879, 23830-20 23951, 26902-27023, 29974-30095, 33046-33167, 36118-36239, 39190-

-45-

39311, 42262-42383, and 45334-45455 of the Epstein-Barr DNA sequence (GenBank accession number: v01555). Only this product of the polymerase chain reaction, found at 122 base pairs, hybridized to the radiolabeled probe.

5 The existing assays for Epstein-Barr DNA were modified so that the assay applied would be as sensitive and specific as the serologic assays are for infection in normal individuals. To achieve this goal a total of 12 mcg of mononuclear DNA in six polymerase chain reactions were evaluated. A long probe was used so that very small amounts of
10 expanded *Bam*H1 W fragment DNA can be detected.

This assay was used in 50 subjects. Of these, 38 individuals that had positive Epstein-Barr virus Viral Capsid Antigen ("EBV-VCA") IgG antibodies (as determined by the assay from Clark Laboratories, Inc.) also expanded the predicted 122 base pair DNA fragment which hybridized to
15 the *Bam*HI W probe from the Epstein-Barr viral DNA sequence. Epstein-Barr virus DNA was recovered in three other subjects whose serologic assays were not positive. In one of these subjects the serologic results for Epstein-Barr virus Viral Capsid Antigen IgG was close to the positive range, as determined in comparison to the calibrator sera provided by the
20 manufacturer. One control had evidence of antibodies to EBV-VCA but no evidence of EBV-DNA as determined by the method described herein.

Neither anti-Epstein-Barr virus Viral Capsid Antigen IgG antibodies nor Epstein-Barr virus DNA was detected in the other seven subjects tested.

25 The new assay has high sensitivity and specificity relative to the serologic analysis. Actually, the direct detection of viral DNA, if true, is a more proximal indication of infection than is seroconversion and is probably a better standard for viral infection than is serology.

The detection of Epstein-Barr virus DNA has proven to be
30 sufficiently reliable for application to the evaluation of the frequency of Epstein-Barr virus infection in lupus and their controls. A matched case-control design was followed. Cases of lupus in children and adolescents (<20 years old) had been enrolled into this experiment as they were

-46-

encountered along with a sex, age (within two years), and race matched control. To control for socioeconomic factors and likelihood of viral exposure, each case was asked to provide a relative or friend to serve as a control. Relatives were preferred over friends. The inventors selected 5 controls for eight cases who did not provide their own control.

The data were evaluated with the Exact Binomial Test for Matched Data. Of the 25 lupus cases, all 25 had been infected by Epstein-Barr virus as determined by the assay for viral DNA and also had antibodies directed against Epstein-Barr Viral Capsid Antigen. Of the 25 matched 10 controls, 17 had been infected by Epstein-Barr virus as determined by the assay for viral DNA. Of the 17 with viral DNA, 14 had IgG antibodies directed against Epstein-Barr virus Viral Capsid Antigen and three did not. One control had no detectable DNA from the virus by the assay and yet had anti-Epstein-Barr virus Viral Capsid Antigen IgG antibodies.

15 To evaluate these data from the most conservative perspective, subjects were required to be negative in both assays in order to conclude that a particular subject had not been infected with Epstein-Barr virus. By these criteria seven of the matched pairs were discordant for infection. All seven of these discordant pairs are discordant in the same way, 20 Epstein-Barr virus infection had occurred in the case and not in the control, which is very unlikely to have occurred by chance ($p < 0.008$)

(Table 5).

Table 5. Matched case-control evaluation of the presence of Epstein-Barr DNA in peripheral blood mononuclear cells from lupus patients (cases) and controls matched for sex, race, and age (+/- 2 years).

Epstein-Barr virus infection		
Lupus Cases	Matched Control	
+	+	18
+	-	7
-	+	0
-	-	0

The probability of this distribution occurring by chance is $p=0.0078$ by the Exact Binomial Test for Matched Data. The odds ratio for this distribution cannot be calculated because of the zero cell. If the usual adjustment of 0.5 is made then the odds ratio is estimated to be $=13$.

These results dramatically confirm the serologic data.

Collectively, these data, the serologic results and the control experiments establish that there is a virtually complete association of Epstein-Barr virus infection with systemic lupus erythematosus.

5 **Example 8.** Antibodies against some Epstein-Barr virus structures are associated with the presence of an autoimmune disease, compositions for diagnostics.

-48-

infection by Epstein-Barr virus, is a major epitope in infectious mononucleosis and in normals (Rhodes, G. et al. J. Exp. Med. 165:1026-1040 (1987)) tends not to be bound by patients with lupus (Figure 7).

The overlapping octapeptides were constructed from the sequence 5 of EBNA-1 (Epstein-Barr virus Nuclear Antigen-1) protein and preliminarily evaluated in four lupus patient sera and four controls. One control had no serologic evidence of having been exposed to Epstein-Barr virus, while the other three have anti-Epstein-Barr virus Viral Capsid Antigen IgG antibodies. All four of the patients had anti-Epstein-Barr 10 virus Viral Capsid Antigen IgG antibodies.

The binding to octapeptides from EBNA-1 (Epstein-Barr virus Nuclear Antigen-1) protein shows dramatically different patterns between the Epstein-Barr virus exposed lupus patients and normal controls (Figure 8). These and other differences could become the basis for diagnostics 15 that predict the risk of an autoimmune disease, that are associated with the presence of an autoimmune disease, and that are associated with particular clinical findings or manifestations. The structures bound by the lupus sera tested are listed in Table 6.

-49-

Table 6. Octapeptides from Epstein-Barr virus Nuclear Antigen-1 bound by the sera from two patients with systemic lupus erythematosus.

-50-

These are taken from the data in Figures 8D and 8E. The peptides presented were bound in one of the sera by greater than 0.450 Absorbance Units. Sequences longer than eight amino acids represent neighboring octapeptides that exceed the 0.450 A.U. threshold. Studies 5 by John Vaughan and colleagues found some peptides of Epstein-Barr virus Nuclear Antigen-1 to be more antigenic in lupus patients than in controls (Petersen, et al, Arthritis Rheum. 33: 993-1000 (1990)). The octapeptides which share sequence with the peptides that were used in the Peterson study are identified with the peptide name used in their study 10 (Table 6). Those peptides which they found to be differentially bound by lupus sera, relative to control sera, are identified with an *.

Other differences in the antibody and cellular responses are expected to be important for the purpose of predicting the presence of (diagnosis) or subsequent risk of an autoimmune disease. Those 15 presented above are examples of structures potentially useful for this purpose.

Assuming Epstein-Barr virus causes some autoimmune diseases, then differences in the immune response against this virus have the potential to predict risk of autoimmune disease and to be an aid to 20 diagnosis and management of autoimmune disease.

Other structures defined by the proteins, glycoproteins nucleic acids, etc., will also be useful for this purpose. Such diagnostic tests can be based upon the relative presence of an antibody, cellular proliferation,

-51-

molecular binding, cytokine production, skin reaction (erythema or induration), cell surface antigen or other measure of activation.

Example 9. Use of a vaccine composition designed to induce a response to prevent or treat an autoimmune disease.

5 Assuming Epstein-Barr virus causes autoimmune disease, then an effective vaccine which induces a protective response against Epstein-Barr virus has the potential to protect the host from the autoimmune disease.

This is particularly true if the structure(s) which induce autoimmune disease is(are) altered or removed from the vaccine.

10 Once infected, this virus is latent and in most, perhaps virtually all, individuals the virus emerges from latency at a low level throughout the remainder of life. The viral infected cells or the immune response required to suppress the virus have the potential to be extremely important in inducing or sustaining the autoimmune disease. Cells latently infected 15 by Epstein-barr virus may also alter the immune response. Consequently, treatments designed to suppress or eliminate Epstein-Barr virus have the potential to ameliorate the symptoms and tissue damage of the autoimmune disease.

Treatments expected to be useful against autoimmune disease 20 include compositions that suppress the emergence of Epstein-Barr virus from latency. Also, agents for gene therapy directed against Epstein-Barr virus will be useful. Biologicals may also prove useful against Epstein-Barr virus by altering the intracellular environment, making it less hospitable to the virus by directly affecting the virus or by making the

-52-

immune response against the virus less prone to support an autoimmune disease process.

We claim:

1. A vaccine for alleviating or preventing autoimmune disorders induced by infection with Epstein-Barr virus comprising Epstein-Barr virus or a component thereof in a pharmaceutically acceptable carrier for administration of the virus or viral component in an amount and mode of administration effective to alleviate or prevent the autoimmune disorders.
2. The vaccine of claim 1 wherein one or more structures of the Epstein-Barr virus are removed or altered to decrease the potential that the vaccine will induce an autoimmune disorder.
3. The vaccine of claim 1 wherein the component of Epstein-Barr virus is selected from the group consisting of peptides or proteins expressed from recombinant DNA or RNA with sequence identity to Epstein-Barr virus, viral DNA or RNA, and carbohydrate components of the Epstein-Barr virus.
4. The vaccine of claim 1 wherein the Epstein-Barr virus comprises the nuclear antigen 1 protein not including a peptide sequence selected from the group consisting of PPPGRRP, GRGRGRGG and RGRGREK.
5. The vaccine of claim 1 in a pharmaceutical carrier for administration by injection.

6. A diagnostic test comprising reagents which can be used to detect levels of antibodies to Epstein-Barr virus, indicators of Epstein-Barr infection of cells, or levels of Epstein-Barr DNA or protein in a patient, and control samples from individuals not at risk of developing an autoimmune disease, and means for determining the differences in levels of a patient and control samples to distinguish individuals at higher risk of developing an autoimmune disease from those at lower risk of developing an autoimmune disease.

-64-

7. The diagnostic test of claim 6 wherein the reagents are used in assays based upon the relative presence of an antibody, cellular proliferation, molecular binding, cytokine production, skin reaction, or cell surface antigen.

8. The diagnostic test of claim 6 wherein the reagents are used to detect antibodies to peptides from Epstein-Barr virus selected from the group consisting of PPPGRRP (SEQ ID NO:1), GRGRGRGG (SEQ ID NO:2), RGRGREK (SEQ ID NO:3),
GAGAGAGAGAGAGAGAGAGAGAGAGAGA (SEQ ID NO:7),
GPQRRGGDNHGRGRGRGRGRGGGRPG (SEQ ID NO:13),
GGSGSGPRHRDGVRPQKRP (SEQ ID NO:14), RPQKRPSC (SEQ ID NO:15), QKRPSIGCKGTHGGTG (SEQ ID NO:16),
GTGAGAGAGARGGG (SEQ ID NO:17), SGGRGRGG (SEQ ID NO:18),
RGGSGGRRGRGR (SEQ ID NO:19), RARGRGRGRGEKRPRS (SEQ ID NO:20), SSSSGSPPRPPPGR (SEQ ID NO:21),
RPPPGRRPFFHPVGEADYFEYHQEG (SEQ ID NO:22), PDVPPGAI (SEQ ID NO:23), PGAIEQGPA (SEQ ID NO:24), GPSTGPRG (SEQ ID NO:25), GQGDGGRRK (SEQ ID NO:26), DGGRRKKGGWFGKHR (SEQ ID NO:27), GKHRGQGGSN (SEQ ID NO:28), GQGGSNPK (SEQ ID NO:29), NPKFENIA (SEQ ID NO:30), RSHVERTT (SEQ ID NO:31), VFVYGGSKT (SEQ ID NO:32), GSCTSLYNL (SEQ ID NO:33), GMAPGPGP (SEQ ID NO:34), PQPGPLRE (SEQ ID NO:35), CNIRVTVC (SEQ ID NO:36), RVTVCSFDDG (SEQ ID NO:37), PPWFPPMVEG (SEQ ID NO:38).

9. The diagnostic test of claim 8 comprising reagents for detection of antibodies to GAGAGAGAGAGAGAGAGAGAGAGAGA (SEQ ID NO:7).

10. The diagnostic test of claim 6 for testing patients identified with or at risk of developing systemic lupus erythematosus comprising control samples from individuals with systemic lupus erythematosus.

11. A method for preventing or alleviating autoimmune disorders induced by infection with Epstein-Barr virus comprising

-65-

vaccinating or administering to a individual at risk of developing, or who has been identified as having symptoms associated with, an autoimmune disorder induced by infection with Epstein-Barr virus,

Epstein-Barr virus or a component thereof in a pharmaceutically acceptable carrier for administration of the virus or viral component in an amount and mode of administration effective to alleviate or prevent the autoimmune disorders.

12. The method of claim 11 wherein one or more structures of the Epstein-Barr virus are removed or altered to decrease the potential that the vaccine will induce an autoimmune disorder.

13. The method of claim 11 wherein the component of Epstein-Barr virus is selected from the group consisting of peptides or proteins expressed from recombinant DNA or RNA with sequence identity to Epstein-Barr virus, viral DNA or RNA, and carbohydrate components of the Epstein-Barr virus.

14. The method of claim 11 wherein the Epstein-Barr virus comprises the nuclear antigen 1 protein not including a peptide sequence selected from the group consisting of PPPGRRP (SEQ ID NO:1), GRGRGRGG (SEQ ID NO:2) and RGRGREK (SEQ ID NO:3).

15. The method of claim 11 wherein the individual has symptoms of or is at risk of developing an autoimmune disorder selected from the group consisting of systemic lupus erythematosus, Sjogren's syndrome, rheumatoid arthritis, juvenile onset diabetes mellitus, Wegener's granulomatosis, inflammatory bowel disease, polymyositis, dermatomyositis, multiple endocrine failure, Schmidt's syndrome, autoimmune uveitis, Addison's disease, adrenalitis, primary biliary cirrhosis, Graves' disease, thyroiditis, Hashimoto's thyroiditis, autoimmune thyroid disease, pernicious anemia, lupoid hepatitis, demyelinating diseases, multiple sclerosis, subacute cutaneous lupus erythematosus, hypoparathyroidism, Dressler's syndrome, myasthenia gravis, autoimmune thrombocytopenia, idiopathic thrombocytopenic purpura, hemolytic anemia, autoimmune hemolytic anemia, pemphigus

-66-

vulgaris, pemphigus, bullous pemphigoid, dermatitis herpetiformis, alopecia areata, autoimmune cystitis, pemphigoid, scleroderma, progressive systemic sclerosis, CREST syndrome (calcinosis, Raynaud's esophageal dysmotility, sclerodactyly, and telangiectasia), adult onset diabetes mellitus (Type II diabetes), male or female autoimmune infertility, ankylosing spondylitis, ulcerative colitis, Crohn's disease, mixed connective tissue disease, polyarteritis nodosa, systemic necrotizing vasculitis, juvenile onset rheumatoid arthritis, glomerulonephritis, atopic dermatitis, atopic rhinitis, Goodpasture's syndrome, Chagas' disease, sarcoidosis, rheumatic fever, asthma, recurrent abortion, anti-phospholipid syndrome, farmer's lung, erythema multiforme, postcardiotomy syndrome, Cushing's syndrome, autoimmune chronic active hepatitis, bird-fancier's lung, allergic encephalomyelitis, toxic necrodermal lysis, alopecia, Alport's syndrome, alveolitis, allergic alveolitis, fibrosing alveolitis, interstitial lung disease, erythema nodosum, pyoderma gangrenosum, transfusion reaction, chronic fatigue syndrome, fibromyalgia, Takayasu's arteritis, Kawasaki's disease, polymyalgia rheumatica, temporal arteritis, giant cell arteritis, Sampter's syndrome (triaditis also called, nasal polyps, eosinophilia, and asthma), Behcet's disease, Caplan's syndrome, dengue, encephalomyositis, endocarditis, myocarditis, endomyocardial fibrosis, endophthalmitis, erythema elevatum et diutinum, psoriasis, erythroblastosis fetalis, fascitis with eosinophilia, Shulman's syndrome, Felty's syndrome, filariasis, cyclitis, chronic cyclitis, heterochromic cyclitis, Fuch's cyclitis, IgA nephropathy, Henoch-Schonlein purpura, glomerulonephritis, cardiomyopathy, post vaccination syndromes, Hodgkin's and non-Hodgkin's lymphoma, renal cell carcinoma, Eaton-Lambert syndrome, relapsing polychondritis.

16. The method of claim 11 wherein the vaccine is administered prior to infection with Epstein-Barr virus.

17. The method of claim 11 wherein the vaccine is administered to an individual who has or has previously had an infection with Epstein-Barr virus.

-67-

18. The method of claim 11 wherein the autoimmune disorder is systemic lupus erythematosus.

19. A method for determining the likelihood that an individual has an autoimmune disorder induced by Epstein-Barr virus, or is at risk for developing such an autoimmune disorder, comprising

obtaining a sample from the individual to be tested,

mixing the sample with reagents which can be used to detect levels of antibodies to Epstein-Barr virus, indicators of Epstein-Barr infection of cells, or levels of Epstein-Barr DNA or protein in a patient,

analyzing the sample, and

comparing the analysis of the sample with results obtained with control samples from individuals not at risk of developing an autoimmune disease to determine if the differences in levels of the individual and control samples indicates the individual is at a higher risk of developing an autoimmune disease than controls who are at lower risk of developing an autoimmune disease.

20. The method of claim 19 wherein the reagents are used in assays based upon the relative presence of an antibody, cellular proliferation, molecular binding, cytokine production, skin reaction, or cell surface antigen.

21. The method of claim 19 wherein the reagents are used to detect antibodies to peptides from Epstein-Barr virus selected from the group consisting of PPPGRRP (SEQ ID NO:1), GRGRGRGG (SEQ ID NO:2), RGRGREK (SEQ ID NO:3),

GAGAGAGAGAGAGAGAGAGAGAGAGA (SEQ ID NO:7),

GPQRRGGDNHGRGRGRGRGRGGGRPG (SEQ ID NO:13),

GGSGSGPRHRDGVRPQKRP (SEQ ID NO:14), RPQKRPSC (SEQ ID NO:15), QKRPSCLGCKGTHGGTG (SEQ ID NO:16),

GTGAGAGAGRGG (SEQ ID NO:17), SGGRGRGG (SEQ ID NO:18),

RGGSGGRRGRGR (SEQ ID NO:19), RARGRGRGRGEKRPRS (SEQ ID NO:20), SSSSGSPPRPPPPGR (SEQ ID NO:21),

RPPPGRRPFFHPVGEADYFEYHQEG (SEQ ID NO:22), PDVPPGAI

(SEQ ID NO:23), PGAIEQGPA (SEQ ID NO:24), GPSTGPRG (SEQ ID NO:25), GQGDGGRRK (SEQ ID NO:26), DGGRRKKGGWFGKHR (SEQ ID NO:27), GKHRGQGGSN (SEQ ID NO:28), GQGGSNPK (SEQ ID NO:29), NPKFENIA (SEQ ID NO:30), RSHVERTT (SEQ ID NO:31), VFVYGGSKT (SEQ ID NO:32), GSKTSLYNL (SEQ ID NO:33), GMAPGPGP (SEQ ID NO:34), PQPGPLRE (SEQ ID NO:35), CNIRVTVC (SEQ ID NO:36), RVTVCSFDDG (SEQ ID NO:37), PPWFPPMVEG (SEQ ID NO:38).

23. A method for screening of therapeutics for prevention or alleviation of autoimmune disorders induced by infection with Epstein-Barr virus comprising

administering the therapeutic to be tested to an animal vaccinated with Epstein-Barr virus or a component thereof in an amount and mode of administration effective to induce an autoimmune response

24. The method of claim 23 further comprising administering the therapeutic to an animal which does not develop an autoimmune response when vaccinated with the same composition effective in another strain of the animal, and determining the difference in response to the therapeutic

25. The method of claim 24 wherein the animals are mice

26. A method for screening for genetic markers or risk factors for development of autoimmune disorders induced by infection with Epstein-Barr virus comprising comparing the responses of different strains of the same species of an animal vaccinated with Epstein-Barr virus or a component thereof in an amount and mode of administration effective to induce an autoimmune response in at least one of the strains and comparing the differences in the genetics of the different strains to identify potential genetic markers or risk factors.

<p>(54) Title: DIAGNOSTICS AND THERAPY OF EPSTEIN-BARR VIRUS IN AUTOIMMUNE DISORDERS</p> <p>(57) Abstract</p> <p>Data consistent with autoimmune disease being caused by Epstein-Barr virus are shown. Based on this evidence, an effective vaccine would prevent the autoimmune disease in those vaccinated, modified or administered so that the vaccine is not itself capable of inducing autoimmune disease. In the case of anti-Sm, structures to be avoided in Epstein-Barr virus-derived vaccine have been identified. Differences have been identified in the immune responses to Epstein-Barr infection between individuals who develop a specific autoimmune disease and those who do not. These differences are used to distinguish those who are at greater risk for developing specific autoimmune diseases from those who are at lesser risk. Assuming Epstein-Barr virus causes autoimmune disease and that Epstein-Barr virus remains latent in the patient for life, reactivation of the virus from the latent state is important in generating or maintaining the autoimmune response that culminates in autoimmune disease. Cells infected with latent virus may also encourage autoimmunity. Based on the understanding that reactivation or latency are important to produce or sustain autoimmunity, then therapies directed against Epstein-Barr virus will also be effective therapies for the autoimmune manifestations of disease for which Epstein-Barr virus is responsible.</p>

INTERNATIONAL SEARCH REPORT

International Application No
PCT/US 98/00342

A. CLASSIFICATION OF SUBJECT MATTER
IPC 6 C07K14/05 C12N7/00 A61K39/245 G01N33/569 G01N33/68

According to international Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

IPC 6 C07K

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practical, search terms used)

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category *	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
Y	<p>RHODES ET AL.: "HUMAN IMMUNE RESPONSES TO SYNTHETIC PEPTIDES FROM THE EPSTEIN-BARR NUCLEAR ANTIGEN" JOURNAL OF IMMUN., vol. 134, no. 1, January 1985, pages 211-216, XP002071115 see the whole document</p> <p>---</p> <p>JAMES ET AL.: "IMMUNOGLOBULIN EPITOPE SPREADING AND AUTOIMMUNE DISEASE AFTER PEPTIDE IMMUNIZATION: Sm B/B'-DERIVED PPPGMRPP AND PPPGIRGP INDUCE SPliceosome AUTOIMMUNITY" J. INTERNATIONAL SEARCH REPORT

In' ational application No.
PCT/US 98/00342

Box I Observations where certain claims were found unsearchable (Continuation of item 1 of first sheet)

This International Search Report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. Claims Nos.: because they relate to subject matter not required to be searched by this Authority, namely:
Remark: Although claims 11-18 are directed to a method of treatment of the human/animal body, the search has been carried out and based on the alleged effects of the compound/composition.
2. Claims Nos.: because they relate to parts of the International Application that do not comply with the prescribed requirements to such an extent that no meaningful International Search can be carried out, specifically:
3. Claims Nos.: because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

Box II Observations where unity of invention is lacking (Continuation of item 2 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:

see FURTHER INFORMATION SHEET PCT/ISA/210

1. As all required additional search fees were timely paid by the applicant, this International Search Report covers all searchable claims.
2. As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee.
3. As only some of the required additional search fees were timely paid by the applicant, this International Search Report covers only those claims for which fees were paid, specifically claims Nos.:
4. No required additional search fees were timely paid by the applicant. Consequently, this International Search Report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

1-5, 11-18

Remark on Protest

The additional search fees were accompanied by the applicant's protest.
 No protest accompanied the payment of additional search fees.

FURTHER INFORMATION CONTINUED FROM PCT/ISA/ 210

This International Searching Authority found multiple (groups of) inventions in this international application, as follows:

1. Claims: 1-5,11-18

Vaccine and method for alleviating or preventing autoimmune disorders induced by infection with Epstein-Barr virus.

2. Claims: 6-8,10, 19-21

Diagnostic test and method comprising reagents used to detect antibodies to a peptide disclosed by Seq. ID 1 from the Epstein-Barr virus.

3. Claims: 6-8,10, 19-21

Diagnostic test and method comprising reagents used to detect antibodies to a peptide disclosed by Seq. ID 2 from the Epstein-Barr virus.

4. Claims: 6-8,10, 19-21

Diagnostic test and method comprising reagents used to detect antibodies to a peptide disclosed by Seq. ID 3 from the Epstein-Barr virus.

5. Claims: 6-10, 19-22

Diagnostic test and method comprising reagents used to detect antibodies to a peptide disclosed by Seq. ID 7 from the Epstein-Barr virus.

6. Claims: 6-8,10, 19-21

Diagnostic test and method comprising reagents used to detect antibodies to a peptide disclosed by Seq. ID 13 from the Epstein-Barr virus.

7. Claims: 6-8,10, 19-21

Diagnostic test and method comprising reagents used to detect antibodies to a peptide disclosed by Seq. ID 14 from the Epstein-Barr virus.

FURTHER INFORMATION CONTINUED FROM PCT/ISA/ 210

8. Claims: 6-8,10, 19-21

Diagnostic test and method comprising reagents used to detect antibodies to a peptide disclosed by Seq. ID 15 from the Epstein-Barr virus.

9. Claims: 6-8,10, 19-21

Diagnostic test and method comprising reagents used to detect antibodies to a peptide disclosed by Seq. ID 16 from the Epstein-Barr virus.

10. Claims: 6-8,10, 19-21

Diagnostic test and method comprising reagents used to detect antibodies to a peptide disclosed by Seq. ID 17 from the Epstein-Barr virus.

11. Claims: 6-8,10, 19-21

Diagnostic test and method comprising reagents used to detect antibodies to a peptide disclosed by Seq. ID 18 from the Epstein-Barr virus.

12. Claims: 6-8,10, 19-21

Diagnostic test and method comprising reagents used to detect antibodies to a peptide disclosed by Seq. ID 19 from the Epstein-Barr virus.

13. Claims: 6-8,10, 19-21

Diagnostic test and method comprising reagents used to detect antibodies to a peptide disclosed by Seq. ID 20 from the Epstein-Barr virus.

14. Claims: 6-8,10, 19-21

Diagnostic test and method comprising reagents used to detect antibodies to a peptide disclosed by Seq. ID 21 from the Epstein-Barr virus.

15. Claims: 6-8,10, 19-21

FURTHER INFORMATION CONTINUED FROM PCT/ISA/ 210

Diagnostic test and method comprising reagents used to detect antibodies to a peptide disclosed by Seq. ID 22 from the Epstein-Barr virus.

16. Claims: 6-8,10, 19-21

Diagnostic test and method comprising reagents used to detect antibodies to a peptide disclosed by Seq. ID 23 from the Epstein-Barr virus.

17. Claims: 6-8,10, 19-21

Diagnostic test and method comprising reagents used to detect antibodies to a peptide disclosed by Seq. ID 24 from the Epstein-Barr virus.

18. Claims: 6-8,10, 19-21

Diagnostic test and method comprising reagents used to detect antibodies to a peptide disclosed by Seq. ID 25 from the Epstein-Barr virus.

19. Claims: 6-8,10, 19-21

Diagnostic test and method comprising reagents used to detect antibodies to a peptide disclosed by Seq. ID 26 from the Epstein-Barr virus.

20. Claims: 6-8,10, 19-21

Diagnostic test and method comprising reagents used to detect antibodies to a peptide disclosed by Seq. ID 27 from the Epstein-Barr virus.

21. Claims: 6-8,10, 19-21

Diagnostic test and method comprising reagents used to detect antibodies to a peptide disclosed by Seq. ID 28 from the Epstein-Barr virus.

22. Claims: 6-8,10, 19-21

Diagnostic test and method comprising reagents used to detect antibodies to a peptide disclosed by Seq. ID 29 from the Epstein-Barr virus.

FURTHER INFORMATION CONTINUED FROM PCT/ISA/ 210

23. Claims: 6-8,10, 19-21

Diagnostic test and method comprising reagents used to detect antibodies to a peptide disclosed by Seq. ID 30 from the Epstein-Barr virus.

24. Claims: 6-8,10, 19-21

Diagnostic test and method comprising reagents used to detect antibodies to a peptide disclosed by Seq. ID 31 from the Epstein-Barr virus.

25. Claims: 6-8,10, 19-21

Diagnostic test and method comprising reagents used to detect antibodies to a peptide disclosed by Seq. ID 32 from the Epstein-Barr virus.

26. Claims: 6-8,10, 19-21

Diagnostic test and method comprising reagents used to detect antibodies to a peptide disclosed by Seq. ID 33 from the Epstein-Barr virus.

27. Claims: 6-8,10, 19-21

Diagnostic test and method comprising reagents used to detect antibodies to a peptide disclosed by Seq. ID 34 from the Epstein-Barr virus.

28. Claims: 6-8,10, 19-21

Diagnostic test and method comprising reagents used to detect antibodies to a peptide disclosed by Seq. ID 35 from the Epstein-Barr virus.

29. Claims: 6-8,10, 19-21

Diagnostic test and method comprising reagents used to detect antibodies to a peptide disclosed by Seq. ID 36 from the Epstein-Barr virus.

30. Claims: 6-8,10, 19-21

Diagnostic test and method comprising reagents used to detect antibodies to a peptide disclosed by Seq. ID 37 from the Epstein-Barr virus.

FURTHER INFORMATION CONTINUED FROM PCT/ISA/ 210

31. Claims: 6-8,10, 19-21

Diagnostic test and method comprising reagents used to detect antibodies to a peptide disclosed by Seq. ID 38 from the Epstein-Barr virus.

32. Claims: 23-26

Methods for screening of therapeutics, genetic markers or risk factors for prevention or alleviation of autoimmune disorders induced by infection with Epstein-Barr virus.
